889, l. Cathartics are often cumulative in their effects; but this will depend much, as with numerous other remedies to which this principle applies, upon the frequency with which they are administered (\$ 556-558). If the interval be short, as about four or six hours, and the same dose be continued, the last may operate with violence, although the preceding had manifested no effect. But this is far from being always true. Indeed, it is often necessary to increase the dose, even when exhibited at these short intervals; and we arrive at a knowledge of all this, and sufficient for the exigencies of the case, whether as to dose, the nature of the cathartic, or time for repetition, by considering the existing condition of the intestinal canal, or other contingent influences, such as jaundice, &c. But here, embarrassments frequently grow out of constitutional peculiarities of patients. These natural peculiarities, in relation to cathartics especially, are often remarkably great; one patient bearing far larger doses, and more active cathartics, than another under apparently the same circumstances of disease; just as in the case of bloodletting (§ 912). I am therefore always in the habit of interrogating patients with whose susceptibilities in this respect I am unacquainted, as to the quantity of salts, or of castor oil, they may be in the habit of using, with a view to their action upon the bowels. This enlightens us greatly as to their probable susceptibility to the action of other cathartics; and, with the object of extending the philosophy which concerns this subject, I will add that this knowledge as to cathartics will not help us with any oth er agent. Every other must be subjected to the same analysis.

* Sec NOTE EE p. 1133.

There is another and important modification of the cumulative effect of cathartics, according to the frequency of their repetition, and which may be said to apply, more or less, to most other remedies whose effects are cumulative (\$ 555-558). We have just seen, that if cathartics be administered once in four or six hours, that effect is variously manifested. But, if the interval be much shorter, the cumulative influence will be more strongly pronounced. This is owing to the persistence of the modified state of intestinal irritability after each successive dose. Each dose, if soon repeated, raises irritability more and more, so that each, in succession, operates more and more. But, if the intervals be long, irritability returns to its natural state, and a larger dose will be necessary to make an impression (§ 137 d, 514 g, 516 d, no. 6, 549-558, 857). The principle now concerned explains the reason why tartarized antimony or ipecacuanha when united with the sulphate of zinc will take effect as soon as the latter. It is the same, too, which brings the permanent tonics into speedy operation when associated with the analogous diffusible stimulants (\S 890 $\frac{1}{2}$, g).

Now, therefore, if the interval be quite short between the doses of a cathartic, their cumulative effect will be more and more strongly pronounced. Thus: if an infusion of senna, or a solution of salts, forming, respectively, one full dose, be taken in divided quantities every half hour, the entire quantity of either will often purge more actively than if the whole of either were taken at once. So, if a grain of ipecacuanha be administered once in four hours, it will generally fail of producing nausea; but if half a grain be exhibited once in two hours, it will be more apt to nauseate. There are peculiarities about tartarized antimony and other agents, in this respect, which have been considered under the designation of vital habit (§ 535, &c., 873).

A common principle applies to all the foregoing cases, is extensively ingrafted upon morbific and remedial agents, and of vast importance to the hand of art. In the cases recited, by the frequent repetition of the remedies we increase progressively the susceptibility of one part or another to their peculiar influences, either directly or by reflex nervous action. We bring the virtues of the different agents more and more into relation with the organic properties; and, when that relation is fully established, the last dose appears to exert, and may

exert, a greater power than all that had preceded it.

889, m. We may now, perhaps, more readily comprehend a part of the philosophy which should govern us where it is mainly an object to remove habitual constipation, and to which a brief reference was made in a former section (§ 556, b). In cases of this nature, there are two primary objects to be kept in view: 1st. To avail ourselves of the cumulative effect of cathartic remedies; 2d. To establish a free secretion of bile, through alterative reflex nervous actions. tain these objects, it is obvious that the cathartic should be administered with a certain frequency, and that it should be of a certain kind. The cathartic should be of the best alterative nature, that it may reach the liver, and establish the most favorable change in the intestinal canal; the last of which has been already stated (§ 556, b). Castor oil is also valuable for this purpose (PAINE'S Materia Medica, p. 37). It is plain, also, that the doses should be so small as not to produce irrication; for this would soon result in positive disease. The most violent agent may be rendered mild by a proper regulation of the dose

It is therefore less the energy of the remedy, than its salutary alterative virtues, that is to be considered. In pursuing the treatment, our object should be to imitate Nature as nearly as possible: that is to say, to produce one free movement, daily, in the adult, and one or two in infants. The remedy, therefore, should be administered at least once in a day; or, if it can be rightly adjusted, evening and morning would be still better, at the beginning of the treatment. By this process we gradually alter the irritability of the intestine and bring it fully into relation with the virtues of the agent; and, as the bile possesses, also, cathartic endowments, we shall have thus adapted intestinal irritability to the action of that natural and now augmented stimulus. The case is parallel, in its philosophy, with that of the emetics and tonics, as stated in the preceding section 889, l. Also, § 516 d, no. 6.

It hence becomes manifest, that, by pursuing this course we shall soon be under the necessity of diminishing the dose with which the treatment was commenced; till, at last, the quantity dwindles away to such minute doses that the stimulus of the bile and the mechanical irritation of the alimentary matter supersede the farther use of the

medicine; or, the minute doses may now become morbific.

It not unfrequently happens, that, at the beginning of the foregoing treatment the doses fail of their intended effect; when some other cathartic, as a little castor oil, or Rochelle salt, should be exhibited, but not enough to operate actively. Their active effect would interfere with the process of bringing the organic properties into a fixed relation with the small doses of the more alterative remedy, and subsequently to their natural stimulus, the bile.

In all this series of influences it is clear enough that a change is established in the condition of the liver; but a not less important one

occurs in the vital state of the intestine (\S 1057 c).

'889, mm. If we now regard, for a moment, the universal system which is pursued of administering active doses of cathartics, in the foregoing cases (§ 889, m), at intervals of two, three, or more days, we shall readily see that different results must follow; while experience teaches that constipation is not often surmounted in this manner. Too much violence is thus inflicted, nature is embarrassed, and is incapable of instituting those salutary changes which we have seen to arise in the former case.—See § 516 d, no. 6, 857.

Nor is it alone the intestine which fails of being diverted from its torpid state. A shock is propagated to the stomach; the liver violently impressed, and natural changes are not instituted in its action, and a continuous flow of increased bile is not established (§ 889, a).

It is readily seen that rhubarb, for the sake of its tonic virtue, may be often substituted for the aloetic and mercurial compound (§ 556, b), or associated with them, or ipecacuanha sometimes intermingled. Or, at other times, it may be greatly best to substitute mild enemas, whose action is explained in section 498, or again to depend upon diet, exercise, running especially, &c. But, a very common error is committed in these cases, as it respects food. It is not considered that the stomach often suffers as well as the intestine; and all the laxative food, as it is called, which is employed with a view of increasing the residuary matter, is apt to inflict a greater injury upon the stomach than any advantage that may arise from its mechanical irritation of the intestine. These are cases, therefore, for a very limited diet of those

things which are easy of digestion, and for the alterative treatment

by medicine, exercise, &c.

889, n. And now as to the time, in a general sense, most appropriate for the exhibition of cathartics, and the philosophy which concerns it (§ 863, d). There is a certain attendant of the human constitution, as already seen (§ 768), which disposes the system to daily periodical excitement. This natural phenomenon takes place late in the after noon, in all parts of the globe. I have considered its application in a pathological sense, and it is of great importance in that double ac-

ceptation as it regards the operation of cathartics.

It is obvious, I say, that the system is in its most irritable and susceptible state toward the decline of the day, and that this period must be the worst for the operation of so powerful an irritant as cathartics, and more especially so if fever or inflammation be present (§ 137, d); though there is a great difference, in this respect, among different cathartics. The most appropriate time for their administration, in a general sense, is toward the decline of the natural evening paroxysm, or between ten o'clock at night, and eight o'clock in the morning. This will also generally bring their exhibition in febrile affections at an early stage of the remission of fever, so that their operation may be over before the access of another paroxysm. The same principle applies to inflammation; for, although there be no manifest exacerbation in the afternoon, the disease is under the natural tendency of the system to a sate of excitement at this period of the day.

At a late hour in the evening, the natural paroxysm is fast on the decline, and this is the most suitable hour for those cathartics whose operation is slow; as calomel, blue pill, aloes, &c.; and if other purgatives be afterward necessary, they may follow in the morning with a speedy effect. In this manner, the repose of the patient is not disturbed, and is conducive to the salutary influence of the highly-alterative cathartics. These cathartics exert powerful influences upon organs that may not be the seat of disease; which is particularly true of the skin. Now this action which is thus instituted in the surface transmits a curative reflex nervous influence to parts that are diseased, and both the impression upon the skin and its salutary reflex nervous actions will be much promoted by the warmth of the bed, by the horizontal posture, and by sleep. For the same reason, if cold should arrest the action in the skin which the cathartic institutes, that organ, suffering this violence, may reflect morbific sympathies upon other parts, and may thus, more or less, defeat the useful effects of the cathartic (§ 514, h).* It is the work, throughout, of reflex nervous action.

But, all cathartics whose operation is speedy should be exhibited at an early hour in the morning, when the irritability of the system is

least, and sleep has had its balmy influences.

ASTRINGENTS.

890, a. Astringents are commonly supposed to act upon physical principles more than any other remedial agents, and that their special operation is analogous to the tanning process (§ 569, b). I shall endeavor, however, to show that Nature is so far consistent with herself. and that all the facts in the case enforce the conclusion, that astringents operate like all other remedial agents upon vital principles, whether they be administered internally, or applied to the external surface; that they operate by so modifying the living properties and actions of the secerning vessels, that redundant secretions of blood, or of other fluids, are arrested in virtue of that change of vital action.

890, b. Let us now look for an illustration of the foregoing to some agent which embraces other virtues in connection with that which is reputedly astringent. There are many of these; such as the sulphate of zinc, the sulphate of copper, rhubarb, &c. We will take the last mentioned, for the sake of indicating, also, its uses in practice. This substance is positively cathartic in certain therapeutical doses, but so stimulating to the system in such doses as to render great caution necessary in its administration in acute inflammatory diseases; while, on the other hand, in much smaller doses it is adapted to many chronic inflammations. Again, in certain other small doses it is a valuable tonic, but still contra-indicated by active inflammation. Lastly, it may act as an astringent in various doses, from its smallest alterative, to its full cathartic dose; operating under particular circumstances of disease as a direct astringent in its small doses, as in diarrhœa, yet, in an opposite state of the bowels, as in constipation, proving an admirable laxative in the same small and repeated doses (§ 889, m, mm); while its wonders cease not even in its full cathartic dose-for now in diarrhea it first operates as a cathartic, and

then shuts up the bowels as an astringent.

Now, to what causes are all these diversified and apparently contradictory effects owing? They depend upon the natural susceptibility of the organic properties to changes according to the virtues of the agents which may act upon them, and their existing state when the agents are brought into operation; and, secondly, as well, also, upon the doses in which they are administered. When the vital conditions are affected in a peculiar way, and under a given combination of cir cumstances, if a vital agent possessing particular virtues be applied, it will so modify or alter the existing morbid state, that new and definite results will follow. Thus, when the intestinal mucous tissue is affected with that condition of disease which results in a preternatural watery secretion, and consequent evacuations, which is called diarrhea, and rhubarb is administered in a certain dose, this substance first impresses the membrane in such a way as to determine an increase of the peristaltic movement; but it simultaneously alters the morbid state of the intestinal mucous tissue in such manner that the unnatural secretion is arrested; while the change which is thus established in the tissue removes the morbid reflex nervous action from the muscular tissue of the intestine, upon which the diarrhœal evacuation in part depended. The diarrhea thus ceases after the rhubarb has acted moderately as a cathartic. The same causation which determined the action of the rhubarb as a cathartic changed the morbid state in such wise as to arrest the farther production of the intestinal fluid, and the preternatural determination of the nervous power upon the muscular coat of the bowels (§ 1062).—See Note Ee p. 1133.

Whether, therefore, the rhubarb purge, or prove astringent, or tonic, a common principle and common laws are concerned throughout; and all the sensible results depend upon certain alterations which the agent effects in the vital properties and actions of the vessels, or tissues, which are the seat of the morbid conditions, or in

which the various phenomena may take place.

Just so it is, also, with the sulphate of zinc, or of copper, or ipecacuanha, when they restrain hæmoptysis by their emetic effect, or when in smaller doses they arrest other hemorrhages, or diarrhœa, or at other times bring about the results of ordinary tonics. Consider, too, the special, but analogous, effects of opium; which, in arresting intestinal secretions, or those of the liver and kidneys, surpasses every astringent. And yet opium has no astringent principle, nor has it ever been supposed that this remedy checks those products by astringing the vessels or condensing the tissues. It arrests them, especially, by so modifying irritability and sensibility that the natural and other stimuli become less operative. And what lets us particularly into the philosophy of this subject is the coincidence in the effects of opium as it respects the simultaneous diminution of the various other products of the abdominal organs; the cause of the diminution of the bile, and of the urine, being the same as that of the diminution of the diarrheal product of the intestine (§ 889 k, 891 d, 891 $\frac{1}{2}$ k).

890, bb. What I have now explained comprehends the whole philosophy of the operation of astringents. When they arrest the discharge of ulcers, or of blood from the stomach, or of any part with which they come in direct contact, it is mostly by their direct action upon the vital condition of the parts. In other cases it is through reflex action of the nervous system. And here we may look at the coincidence in results between the application of an astringent to a suppurating surface and as the same discharge is arrested by a tonic, or by exercise, or change of air, &c. (§ 227, 740, 902 m). It is the change of action upon which the cessation of the various products depends, and this change may or may not be attended by a vital contraction of the secerning vessels, or of the vessels of any tissues upon which the agents

may exert their direct effects.

Other remedies, such as loss of blood, and that one of a negative nature, cold, which often surpass the pure astringents in arresting effusions of blood, &c., may be brought to the same interpretation of the modus operandi of those astringents. And so the mind itself (§ 740 a).

890, c. When astringents are applied to outward surfaces, as to leech-bites, wounds, &c., they are called *styptics*; and in relation to those agents which are designed for the purpose of arresting external hemorrhages only, there are many which act mostly upon mechanical principles; either by pressure upon the bleeding vessels, as with lint, agaric, cobweb, &c., or by coagulating the blood which exudes from the part; while they also stimulate the bleeding vessels to contract.

890, d. Astringents are one of the classes of remedies which have been greatly abused, as well as applied with little reference to the pathological states they are designed to correct. Hemorrhage from every part, frequent discharges from the intestine, whether watery, bilious, or mucous, the discharge in gonorrhæa, leucorrhæa, &c., are treated by vast numbers according, alone, to the physical conceptions of the action of astringents; and those agents, therefore, are indiscriminately applied to all the foregoing conditions. Beyond this consideration, the discharge alone is an object of attention; the disease appearing to consist in this particular symptom. Many of the preternatural effusions depend upon inflammation or congestion, which astringents rarely fail to aggravate. And yet nothing is more common than the exhibition of those agents in these pathological conditions

without any antecedent treatment by other remedies. It is a common practice, for example, to exhibit the acetate of lead, or some other pure astringent, for a moderate hæmoptysis. The effusion, being instituted by nature for the relief of the congestive state of the lungs in which it originates (805, 1019), and violently arrested by the astringent, is counteracted in its great final cause. But astringents not only inflict that evil, but are also apt to increase the pulmonary affection by a direct morbific action; just as they increase dysenteric inflammation when they establish the change by which the redundant secretion of mucus is arrested. A very frequent ultimate consequence of the former untoward treatment is tuberculous phthisis. This practice has received a great impulse in recent times from morbid anatomy, especially as promulgated by Louis and Andral, and carried forward by British pathologists; who deny the dependence of tubercle upon inflammation. Nor can we desire a better proof of the importance of rendering all such pursuits entirely subservient to the demonstrations of living Nature (§ 756. Also, Med. and Physiolog. Comm., vol. ii., p. 608-634, 743, 744, 748, 780-782, 799).—Note F p. 1114.

Instead, therefore, of the foregoing mal-practice, along with the simultaneous use of a stimulating diet, these patients, if the hemorrhage be small, should be treated by bloodletting, or small doses of tartarized antimony or ipecacuanha, blisters, &c. These agents arrest the effusion, and so far they exert the effect of astringents. But they do more. They alter the morbid states in a mode which Nature was attempting; while the real astringents alter them for the worse; though a cessation of the hemorrhage may be equally the result of either method of treatment (§ 150, 151, 732 b, 733 e, 862-864, 892 $\frac{4}{5}$ d, g)*

There can be no sound practice till hemorrhagic effusions are recognized as the result of a secreting process, instituted by morbid states. The proof is abundant; but it is enough that we witness the consequent relief of disease, and apply ourselves to the analogy in this respect with what is known of redundant effusions of bile, of serum, &c., and which none can fail to recognize as salutary means employed by Nature. These hemorrhages, too, are analogous to menstruation, and here, as there, a great final cause lies at the foundation. There is, therefore, no more propriety in arresting hemorrhage, unless excessive, than in attempting to interfere with the natural function.

890, e. In the advanced stages of fever, and of other severe forms of disease, hemorrhages have been often followed by death. And here it is that hemorrhages have raised the greatest apprehension of their fatal tendency. But, it is very rare that it is the hemorrhage which destroys (§ 1019). It is only a symptom, at this advanced stage of the malady, significant of a fearful condition of disease. which, in itself, in a vast proportion of cases, is the true cause of death (§ 805, 863). The cause, therefore, is too apt to be mistaken, the blame too often attributed to a kind effort of Nature to throw off the deadly weight; and Nature would much oftener succeed by this depletory process were it not for the interfevence of art with its mischievous astringents. It is, however, always a fearful symptom in the advanced stages of acute disease. But, bad as it is, it should be hailed as the best possible event that can happen. The effusion comes directly from the congested parts, and if any thing can relieve them, it must be this spontaneous effort. Art cannot now interfere

* The record should be made that tonics and stimulants are now generally appiled to this as to most other maladies.—Notes F, EE, FF, GG, II, MM.—1865.

with bloodletting. The golden opportunity may have been allowed to pass, either from ignorance, or fear, or from the difficulties of the case (§ 569, 960, 964 c). Nature, alone, can now institute the great remedy; and here it is that we so often witness the safety with which she makes her wonderful demonstrations of cure, and rebukes the timid practitioner. But she has now her own way of operating. She has taken the business of rational treatment upon herself, and out of the hand of art; for now it is that quarts of blood may flow away from the intestine, and triumph over disease, when bloodletting would be perfectly useless, and the abstraction of a dozen ounces of blood would probably be fatal. These are lessons from Nature of everyday occurrence, and should not be lost even to such as are incapable of appreciating disease, or who may be imbued with prejudice, or haunted by fear, in respect to the great remedy whose timely application would save them from the consternation of witnessing a natural outpouring of blood, and from the mortification of discovering that there may have been an important error in treatment.

These are cases which require, in all respects, a great precision of treatment. Where Nature may have laid the foundation of cure by hemorrhagic effusions, a slight error in practice may be fatal. And here, again, the fault is apt to be laid at the door of Nature, and thus the disposition to interfere with astringents is more and more increased. Nevertheless, we should watch these effusions with vigilance; and, whenever they appear to be transcending the exigencies of the case, or the ability of the system to bear them, we should endeavor

to restrain them by appropriate astringents (§ 805).*

890, ee. Those philosophers who justly refer capillary hemorrhage to a secretory process have distinguished the condition into active and passive; of which hæmoptysis is an example of the former, and that which was considered in the last preceding section, of the latter. But, this distinction is as clearly unfounded as that of active and passive inflammation (§ 752, &c.). Here, as there, the varieties are nearly on a par in respect to the pathological cause. The differences which exist among them are owing to only slight modifications of that essential cause. The modifications, however, are such as may require variations of treatment; one of them the antiphlogistic, another the antiphlogistic and astringent combined, and another the astringent alone. They are thus seen to run into each other, and they offer problems where it is the nicest point to determine whether we shall bleed and purge, or administer an astringent.

890, f. When hemorrhage supervenes upon chronic forms of disease, it commonly happens that it must be great to overthrow the obstinacy of habit; and the triumph of Nature is often thus displayed in the hæmatamesis which is set up by aggravated indigestion.

The hemorrhage attendant on tuberculous phthisis is a relief to the sufferer; but not often more than temporary. Nor can we now hope to do much by co-operating with Nature, any farther than to moderate the activity of disease by a non-stimulant diet, and blisters to the chest, or by general or local abstractions of blood where the quantity expectorated may be small. Astringents are always pernicious in these cases, unless the hemorrhage be excessive; and even then we shall generally fail to arrest the effusion on account of its connection with a serious lesion of organization. These, therefore, are cases

^{*} Notes Ff p. 1135, Gg p. 1138, It p. 1139. Also, § 1019.

which sometimes prove suddenly fatal by the quantity of blood ef-

fused, or by its choking up the air-cells.—Note F p. 1114.

890, g. Cases of the foregoing nature (§ 890, f) appear now and then as consequences of badly-treated pneumonias, especially the congestive variety, or what is called typhoid pneumonia. But, we rarely witness any thing more than an expectoration of bloody mucus in the common form of the disease, or even in the congestive, if the treat-

ment have been of the proper antiphlogistic nature.

890, h. Again, nothing is more extensively employed in the treatment of dysentery than rhubarb, and nothing more injuriously (§ 150). Its administration proceeds upon the erroneous views of the modus operandi of astringents and the want of a proper reference to the pathology of the disease. As that pathology consists in active inflammation, it should be manifest that rhubarb is one of the worst agents that can be devised; since it possesses not only the virtue of a true astringent, but is stimulant to the whole circulation, irritant to the whole mucous tract of the intestine, now morbidly susceptible throughout its length from the severe and specific inflammation of its inferior portion (§ 137 d, 398), and if the agent arrest the discharge, it is commonly by increasing and otherwise unfavorably modifying the inflammatory condition (§ 1062).

As in the foregoing case of hæmoptysis, therefore, we should have recourse to direct antiphlogistic means; and the cathartics employed should be of the least irritating nature, and then, only in cautious doses. But, they should be also of an alterative nature, and such as will reach the liver as well as the intestine. In a general sense, castor oil is the best (Paine's Materia Medica, p. 45). Also, § 1057 l.

If we now consider that ipecacuanha is the best internal remedy for dysentery, and the best for hæmoptysis, and that common tablesalt is one of the best for the latter affection, it will help us greatly to the knowledge we are seeking as to astringents, and lead to many practical advantages.—See Ergot & 892\frac{2}{3} \, \text{0}; \text{Note Gg p. 1138.}

S90, i. Rhubarb, opium, and other agents which arrest redundant secretions, are often highly useful in some forms of diarrhæa, and sometimes in chronic discharges of mucus; but these products depend upon various pathological states, and whether astringent remedies will be useful or injurious will depend upon the precise nature of the disease (§ 150, 670–674, 733 f). In the simplest forms of diarrhæa they are more or less useful; particularly rhubarb, and that agent, chalk, which possesses no astringent virtue, but brings about the prominent result of an astringent merely by neutralizing some irritating acid. But soda or potass would not answer, since these irritate by their own virtues, and still more so by forming purgative salts within the alimentary canal. Saline cathartics are, therefore, also improper, and, moreover, scarcely extend their salutary permanent effects beyond the intestinal canal in cases where they are admissible (§ 1061).

890, k. But, even in the simple forms of diarrhea, there is variety as to the exact nature of the morbid condition, which demands, in different cases, a choice of astringent remedies (§ 150, 672-674, 733 f, 863 d). One variety will be greatly benefited by rhubarb and chalk, but aggravated by opium. To another opium is exactly suited, as in pulmonary phthisis; and in such rhubarb may be detrimental, and pure astringents useless. To another variety, as in some old chronic

cases, the acetate of lead may be best adapted; and to others the pure astringents, such as kino, catechu, geranium, &c., when all other means which I have indicated would be either useless or injurious.

890, l. The foregoing examples illustrate variously the general principles which are propounded in this work. But, the variety of illustration may be greatly extended in respect to the remedies now before us. It often happens, for example, that frequent watery dis charges are owing either to inflammation of the intestinal mucous tissue, or to a state approaching inflammation; as in cholera infantum. Here, all astringents are inadmissible; and, if the case be cholera infantum, such is the peculiar nature of its predisposing causes (§ 650-653), that there is nothing comparable with the mild chloride of mercury in doses varying from the twentieth to the eighth of a grain, once in four to twelve hours; perhaps, also, with a little chalk and the camphorated tincture of opium along, to neutralize an acid and to allay intestinal irritability. But it is the mercurial agent which does the work, by breaking up the morbid condition. Calomel, therefore, in such cases, is just as much an astringent as alum, or the acetate of lead, or catechu, in other cases of a modified pathology (§ 150, 151,

863 d). Will Chemistry explain (\S 892 b)?

890, m. Gonorrhæa is another example, and another form of inflammatory disease, where great suffering, and prolonged sickness, are induced by the want of a proper knowledge of the operation of astringents, and a proper discrimination as to the particular state of the pathological condition when the remedies are applied (§ 672). preternatural discharge is apt, indeed, to be regarded as the disease; or whether so or not, it is a common practice to resort, at once, to astringent remedies, internally and by injections. Such, however, is the force of inflammation, and morbid irritability so strongly pronounced, that a direct antiphlogistic treatment should be at least premised; when, also, it will be commonly found that it has superseded the necessity of astringents. And here, again, we may remark how the coincidence in effects between the internal use of copaiba, or cubebs, and injections of an astringent nature, denotes a common mode of action, and places the whole upon vital ground. The frequent salutary effect of the nitrate of silver when employed as an injection in the early stage of gonorrhea, and its pre-eminent advantages in leucorrhæa, go to confirm the same philosophy (§ 150, 151). This substance has no astringency, in the proper acceptation, but operates in its own wonderful way in breaking up the inflammatory state upon which the discharge depends.

890, n. And then as to leucorrhæa. How badly is this affection often treated by astringents, internally and externally, and also by tonics! And all this, mainly, because the disease happens to have, for one of its symptoms, a discharge from the vagina, and is supposed to depend upon debility of the general system, and relaxation of the mucous tissue; a sort of mechanical exudation from a flabby membrane that tonics and astringents may condense and strengthen (§ 409 i, 410, 569). But, if we look at the inflammatory nature of this affection, there will be no difficulty in understanding how these agents, and the usual stimulating diet, inflict their injuries. And now, if we consider that cantharides is the best internal remedy for leucorrhæa, another luminous guide will be obtained to a right apprehension of

the mode in which astringents may check, for awhile, those discharges which they may ultimately increase, or others, in other cases, success-

fully and permanently.

890, o. Let us now consider the remarkable manner in which certain agents will arrest a copious excretion of sweat, and we shall learn still more distinctly that astringents operate through reflex nervous actions; and thus be guided to the only intelligible purposes for which they should be employed, and carry this knowledge throughout the breadth of the Materia Medica.

Thus, then; here is a patient affected with pulmonary phthisis, who rises in the night to shift his wet for dry linen. But this inconvenience may be stopped at once by a few drops of sulphuric acid; and opium will often do the same. The acid and the opium, however, produce very different impressions; though each arrests the sweating by certain vital influences. One may be beneficial, while the other is injurious, and vice versa, according to the exact combination of pathological circumstances when the agents are administered. In other diseases, and where the skin is dry, opium will induce perspiration; and it accomplishes this through the same laws as when it arrests the excretion. And, if we now observe the apparently contradictory philosophy when opium simultaneously checks the products of the liver and kidneys and increases that of the skin, we gain yet farther light as to astringents, penetrate to the common laws which are distinguished by opposite results, and go to the work of cure as the mechanic when he elicits countervailing movements from a common principle, or a common power, whose attributes are known (\S 863, d).

The vegetable kingdom supplies many astringents from which a substance is derived under the name of tannin; and hence, in part, the physical rationale of their modus operandi upon living beings. It is supposed that their astringent virtue resides in this tannin; and this may be so where the principle may be elaborated. But, there are numerous substances of active astringent virtues from which nothing analogous to tannin can be derived; such as the acetate of lead, and, indeed, all the mineral substances belonging to the group of astringents. We see, therefore, that the effect of the astringents themselves is not due to any coincidence in the constitution of these substances; and yet, notwithstanding the great differences among them, they may all bring about a common result (§ 150, 892 b, 892½ v).

It is not alone to certain pathological states that result in redundant effusion that astringents are applicable. Certain conditions of inflammation, especially of external surfaces, are often greatly relieved by their local action. Acetate of lead is one of the best remedies, externally applied, for inflammation of the skin, of the eyes, &c. Sulphate of zinc, also, for conjunctivitis, the mineral acids or vegetable astringents for inflammation of the tonsils. These are active astringents, and the variety in their effects, according to the nature of the pathological conditions, whether employed internally or externally, declare their physiological action, and call upon the practitioner to study well the capabilities of each one. Nay, more; their variety of action when applied externally is not less than what we have seen from their internal administration. The acetate of lead, for example, may speedily relieve certain conjunctival inflammations, when such modifications of inflammation would be greatly aggravated by the sulphate of zinc;

but, in another case apparently alike, the sulphate of zinc will answer a better purpose. The nitrate of silver, however, or blisters, or leeches, may be well adapted to all the modifications. But here is a case, apparently the same, in which all the foregoing means have failed entirely. On pushing inquiry, however, we learn that in the generation preceding the last there prevailed the scrofulous diathesis. We accordingly resort to iodine, and the inflammation yields as under the influence of some magic power (§ 137 e, 150, 151, 851 b, 863 d).

Now, it is of vast practical importance to consider that the foregoing differences in results depend mostly upon slight shades of difference in the inflammatory states in the several cases (§ 150, 662, 673). And who can mistake the common nature of the modus operandi of

all the agents employed (§ 137, e)?

890, p. It is important, therefore, to understand that no two astringents are exactly alike in their effects, and that the property which is recognized as such may be associated with other active virtues in the same substance, by which the astringent is variously modified; while, as in compound medicines, the several virtues act as a whole, that which is most predominant giving the greatest determination to the nature of the impressions that may be produced (§ $188\frac{1}{2} d$, 889 k, 892). This variety, it appears, adapts these agents very variously to different forms of disease. When, therefore, a pure astringent is only required, such as may possess tonic or stimulant virtues should, obviously, be avoided. Remarkable examples of this nature, associated also with other virtues, occur in rhubarb, cinchona, the muriated tincture of iron, &c. Hence there is a great range of choice among remedies which may be selected to answer the intention of an astringent, in its strict acceptation. This has been already variously illustrated, as in the example of rhubarb. But we will have an exemplification in the Peruvian bark, an infusion of which, on account of its specific febrifuge virtue, would be exactly adapted to diarrhea attendant on intermittent fever; or quinine, perhaps, would be preferable if the disease be recent. In such cases a pure astringent would be useless; which farther illustrates the operation of astringents, as it does, also, the distinctions between tonic, astringent, and febrifuge virtues.

But, the foregoing are broad shades of difference in pathological conditions. In very many cases where there is a great approximation in the pathological states, in many modifications of inflammation, it is often important to apply a certain remedy of astringent virtue in pref-

erence to others.

890, q. We may now see that certain astringents may be best suited to certain organs to which they are addressed than to other parts (§

133, &c., 140, 150).

But these agents are so much circumscribed in their uses, that it is no longer an object to pursue the inquiry. What has been said is more with a reference to bring these remedies within the pale of medical philosophy, and to illustrate that philosophy; and, in so doing, to prevent their misapplication. Those which are associated with other virtues are mostly wanted; such as rhubarb, cinchona, the sulphates of zinc and copper, &c., and these, mainly, for the sake of those virtues,

PERMANENT TONICS, AND DIFFUSIBLE STIMULANTS.

890½, a. Tonics may be regarded as a counterpart of the antiphlogistics. From the circumstance, therefore, of the latter occupying the high places in the materia medica we may come, at once, to the conclusion that the former are comparatively of very limited importance. Indeed, it is only in the advanced, or in the declining stages, of acute diseases, or in certain states of chronic affections, that tonics can render much service.—Note Ee p. 1133.

No remedial agents, however, have been more extensively employed, and therefore none which have been so extensively injurious (§ 569, e). This misapplication of the Materia Medica has arisen, as in other cases, from erroneous theoretical views of disease, and mistaken notions of the modus operandi of remedies (§ 854 bb, 863 d, 892 b, 904 d).

890½, b. In considering the uses of tonics it should be borne in mind that they have but a very limited range of curative influences; and that, in a general sense, they do but invigorate organic actions which have been reduced by prolonged disease, and where there is either no great amount of absolute disease, or where nature is already in the way of the restorative process, or where that process may only require an invigorating impulse to start it into existence. Such are the uses of tonics.—Note F p. 1114.

By now regarding the true mode in which these intentions are ac complished, and the absolute influences which are exerted by tonics, we shall come to a just apprehension of their relations to morbid states, and be better qualified to avoid them where they may be injurious.

 $890\frac{1}{2}$, c. Tonics are commonly supposed to act upon mechanical principles, by bringing into close apposition the molecules of which the living tissues are composed, and attempts have been lately made, as at former times, to demonstrate the truth of this conjecture by experiments upon dead tissues (§ 569, b). This has led many to confound the virtues of tonics with those of astringents. But, we shall find that here, as in all other cases, Nature is consistent, and that tonics bring about their results like other remedial agents; that here, as in all analogous instances, there is no departure from Unity of Design (§ 137, e). A few plain illustrations will place the operation of

tonics in its proper aspect.

8901, d. Thus: on referring to an example already stated for another purpose, we cannot fail to observe that the increased warmth of the skin, and muscular vigor produced by animal food as soon as it enters the stomach, are due to the same causation as the analogous effect of alcoholic stimulants, and that both must be expounded upon vital principles (§ 512, b). Those speedy effects manifestly depend upon vital impressions exerted upon the mucous tissue of the stomach, and their transmission by reflex nervous action to other parts. They are variously pronounced according to the exact combination of circumstan-The food will display itself most distinctly in such as have suffered its privation, and where the surface is chilled; the wine where it is least employed (§ 535, &c.). By varying these incidental influences a corresponding variety will obtain in the results. Employ the food or the wine in febrile and inflammatory states and the same manifestations take their rank among the violent phenomena of disease. Now, here is the whole principle which is relative to the action of

tonics. These agents produce the same effects as the foregoing causes, They are the same, or sufficiently so for my present purpose, in the natural state of the body, and are modified in the same manner when employed in fever and inflammation. The fatigue incident to hard labor is instantly relieved by nourishment or by wine. The influences here are exactly analogous to the vigor which is imparted to the voluntary muscles by tonics in cases of indigestion. In the former case the powers of the stomach and the animal frame have sunk under fatigue (§ 855); in the latter from disease. The food and the wine in one case exalt those conditions; and, from the analogy in the influences which are established by tonics in the other, we know that a common mode of action has obtained throughout (§ 137 e, 151). But, the tonic goes yet farther, and brings about a change in the organic state of the stomach, since food will not remove the condition upon which its indigestion depends. The tonic, therefore, is an alterative stimulant. In all the cases the voluntary muscles are suddenly or gradually invigorated by reflex nervous actions propagated from the stomach. It is the same with the tonic as with the food or the wine. No sooner has the dyspeptic swallowed the first dose of bark than he tells us that his strength is coming as by enchantment. The tonic, also, like the wine, increases the desire for food; and if this effect can be no more interpreted by the physical doctrine than the former results, it may be safely concluded that every other problem offered by tonics falls within the philosophy of vitalism (§ 500, 516 d, no. 6, 350, no. 94).

It is now an easy matter to institute analogical demonstrations of the physiological operation of tonics, as in former cases, that of astringents, for example (§ 890). For this purpose ipecacuanha and the nitrate of silver may be taken; neither of which has any tonic virtue, while the former is contra-stimulant. But these agents are appropriate to the same states of indigestion as the tonics, and bring about the same results (§ 904, d). Or, take a mental cause for an exactly similar parallel, which may be seen in the effects of some agreeable intelligence, which, no one can mistake, has imparted, on the instant, a keenness of appetite, a vigor of digestion, and an exaltation of muscular strength, which had not been enjoyed for a month or a year (§ 137 e, 227, 512, 514 h). Or, place the same individual on board a vessel, or give him an airing by land, and the first hour, perhaps, will have brought with it far greater improvement of digestion and of muscular strength, than would have been imparted by cinchona, or any

other tonic, in a month (§ 150, 657 a, 847 g, 856 a).

890½, e. As to the extent in which tonics may act as alteratives, that, as in respect to all other remedial agents, will depend upon the departure of the organic properties and actions from their natural type. As in all other cases, also, the useful effects will depend upon the nature of the morbid changes. But these conditions, in their relation to tonics, are not often constituted by any great deviations from the natural states. In most other instances tonics are morbific (§ 137, e). If they happen to be useful in active forms of disease, it is a random hit (§ 756). Their operation, however, even then, comes under the same principle as when they produce favorable results upon chronic derangements (§ 901). Sometimes, therefore, when active disease becomes prolonged, and the susceptibilities of the parts affected turned a little from the incipient pathological state and under the influ-

ence of vital habit, tonics will prove less frequently detrimental, or may be so far curative that we venture to associate them now and then with the direct antiphlogistics, to obtain their mixed influence. It is often useful to combine them, especially the vegetable, in the form of infusion, or, perhaps, of tincture, with the mild cathartics that are adapted to the advanced stages of disease, just as we have seen of the union of rhubarb with saline purgatives (§ 872, a). In such cases, they not only prevent any prostrating effects of the cathartic, but are positively remedial by going to the vital condition of organs (§ 137 d, 150, 569 c). And here, as in the case of rhubarb (§ 872, a), we may reverse the order of indications, and suppose that a tonic may be useful if it can be prevented from stimulating injuriously. object may be often attained by uniting a mild saline cathartic, or, administering small alterative doses of tartarized antimony. practice, in respect to antimony, is often highly useful in the treatment of intermittent fever, where the tonic virtue of cinchona, or quinia, interferes with the febrifuge virtue; while, at the same time, the antimony does its important work as an antiphlogistic alterative. Both of the agents, in these cases, are principal remedies. But it is the febrifuge, not the tonic virtue, which makes the salutary impres-The former is positively morbific, and may not only defeat the febrifuge action without the counteracting influence of antimony, but aggravate greatly the whole condition of disease. And this, by the way, is a distinct exemplification of the existence of those two opposing virtues in cinchona; while in the other forms of disease it shows itself in the aspect only of one of the best tonics (§ 137 d, 150, 535, &c., 672, 673, 675, 756, 847 g, 848, 854, 863 d, 867, 889 k, 890 b).

 $890\frac{1}{2}$, f. But I say, again, that these agents are never wanted, in their relation to diseased states as tonics, in the early stages of any disease whatever; and, however they may now and then succeed (§ 756), they are generally prejudicial. If employed in certain forms of fever or inflammation in which tonics possessing febrifuge virtues, like cinchona, are not indicated, they endanger life (§ 150, 569 e, 621 a, 652 c, 662, 847 g, 848, 863 d). I think I shall have justified this assertion throughout the extent of these Institutes. But, in failure of this I have only to point out the results of the Brunonian doctrine of disease, which prompted the tonic and stimulant treatment to so great an extent that it has been computed to have destroyed a greater number of the inhabitants of Europe, in the first forty years of its prevalence, than all the wars of that sanguinary period (§ 621, a, 1068).

 $890\frac{1}{2}$, g. There are great resemblances between the virtues of tonics and diffusible stimulants, in their common acceptation; but there are also important distinctions. In instituting comparisons, therefore, between them, or of all other remedies, they should be regarded in their just relations to morbid states; for in this adaptation alone can they be remedial. We shall thus find that both classes of remedies are more or less applicable to the same conditions of disease, and that, on account of the differences that exist in their remedial virtues, it will be often useful to combine them together (§ 863 d, 889 k, l). In their proper therapeutical acceptation, tonics make their impression much more gradually, and more permanently, than diffusible stimulants; observing, in this respect, the same distinction that subsists between animal and vegetable food (§ 441 c, $890\frac{1}{2}$ d). When, also,

tonics are useful, their effects are far more profound than those of diffusible stimulants. But this is not true of their morbific effects under circumstances of existing disease; since wine, and especially more ardent spirits, taken in any acute inflammation or fever, not only produce their usual more rapid impressions, but exasperate the morbid states to far greater degrees of intensity than any of the permaneut tonics. The principle holds, also, in chronic diseases when tonics or

stimulants prove morbific (\S 137, d).

The foregoing peculiarity of tonics fits them admirably to certan chronic forms of disease where the strong influence of a long-protracted morbid habit is to be surmounted (§ 535, &c.). Stimulants will not reach these conditions with sufficient alterative effect, or they may act with too much rapidity where a diseased habit is obstinately established, and where long-continued organic actions of a morbid nature can be surmounted only by the slow operation of favorable causes. But, in these obstinate conditions the permanent tonics may not act with all the rapidity that may be useful; and then we associate some of the transient stimulants with them, by which the morbid states are rendered more susceptible of the effect of the tonic remedy, just as by uniting the sulphate of zinc with ipecacuanha the latter will exert its emetic effect simultaneously with the former; all of which contradicts the doctrine of absorption (§ 137 d, 889 k, l, 904 bb).

Again, however, some of the tonics possess, also, the virtues of transient stimulants, such as the cinchonas; and these compound attributes suit them well for those conditions of which I was last speaking, or for irritable states of the stomach when tonics are wanted, but are apt to nauseate (§ 150, 889 k, 890 b). In these conditions, a cold infusion of cinchona, whether as a febrifuge or as a tonic, surpasses its alkaloids on account of the presence of a volatile oil by which the stomach is promptly and gently stimulated, and thus enabled to bear

the tonic influence of the bark.

890½, h. The suggestions which have been now made let us at once into the reason why all the tonics and stimulants may be converted to useful purposes in disease, and why it is greatly otherwise with cathartics and emetics. In the last instances there are far greater diversities in their curative and morbific virtues, and they are far more of an alterative nature than such as appertain to tonics and stimulants. There exist, indeed, among cathartics and emetics many agents that can rarely be applied to any morbid conditions without increasing the existing evil or engendering new ones. In this respect, all the tonics and stimulants, when employed in active febrile or inflammatory states, are on a par with the most irritating cathartics and emetics. Their effect then goes deep; which admonishes us, more and more, to study well the relations of remedies to diseased conditions, and to discard all the conclusions which have been drawn from an observation of their effects upon man in health (§ 137 d, 150, 662 a, 675, 854 bb).

Nevertheless, the same principle of diversity applies to the several members of the classes of tonics and stimulants; but it reaches them in a very inferior degree (§ 52, 650). Since, therefore, there are no groups of remedies so closely allied in their virtues throughout as tonics and stimulants, there are none which, throughout, bring about results in the treatment of disease that so closely resemble each other

(§ 863, d).—Note Ee p. 1133.

We thus come to understand why all the substances which compose the classes of tonics and stimulants may be more or less useful, and that no one of them is an excrescence upon the Materia Medica; notwithstanding the vast abuses to which they have been subjected, and the immense mortality of which they have been the conspicuous causes (§ 569 e, 621 a). We are also thus led to the knowledge that one tonic, or stimulant, will often answer a better purpose than another; and we find, on applying ourselves to an observation of Na ture, that experience confirms all the other premises. We have just seen an example of this in cinchona, and it is a striking general distinction, that the vegetable tonics are best adapted to the prostrate conditions which follow long-protracted acute diseases, while the mineral, especially the preparations of iron, are suited to chronic maladies, such as indigestion. Here, however, the vegetable tonics may be equally appropriate, while the mineral ones are not so to the direct sequelæ of acute maladies.

NARCOTICS.

891, a. Narcotics are agents which affect, especially, the nervous centres, and are, therefore, also denominated cerebro-spinants.*

In my Arrangement of the Materia Medica I have divided them into six groups or orders, according to their special influences upon the nervous system. Narcotics stand in a group by themselves; and the remaining five consist of antispasmodics, tetanics or cerebro-spinoexcitants, moto-paralysants, senso-paralysants, and cerebro-spino-depressants. These distinctions are more or less observed by others.

Some of the narcotics, however, possess also the virtues of other groups, and vice versa; and, therefore, in conformity with this compound endowment, the same agents appear under the several appropriate of the

priate denominations.—Note Nn p. 1141.

891, b. The most useful of the narcotics are the great agents by which pain is immediately assuaged, restlessness subdued into tranquillity, and wakefulness converted into refreshing sleep. Such, therefore, may be taken as the definition which I apply to narcotics, and without special reference to the profound influences which they may exert upon organic functions, or to other useful effects.

But, all narcotics do not equally produce their several effects. Some of them are more remarkable for diminishing and relieving pain, and are called *anodynes* (§ 194, &c.). Others produce sleep more particularly, and are known as *soporifics*. Others allay irritability and diminish vascular action, local and general, in a more decided manner than the rest, and are called *sedatives* (§ 188, &c.).

Such are the denominations in common use; but they are somewhat defective. All the soporifics, for instance, are also anodynes, and most, though not all of the anodynes, are more or less soporific. There are, also, many sedatives which do not rank at all among the narcotics; to which, indeed, the most powerful do not belong, such as bloodletting, hydrocyanic acid, tobacco, &c., and of which bloodletting is the only one of much value in the treatment of disease, but that one emphatically and justly denominated the remedium principale. The sedatives, therefore, which fall under the denomination of narcotics, possess, also, anodyne or soporific virtues.

891, c. We have seen how extensively large classes of remedies * This term is deficient in not embracing the sympathetic nerve, which is mainly interested in the nervous influences upon organic functions and products (§ 113, 461).

have been perverted in their uses, and have yet to consider the no less common neglect or misapplication of bloodletting. There is no other way of enforcing their claims to a just consideration. In respect to the agents now before us, there is a yet smaller class who are equally unhappy in their estimate of their virtues; and, while the stimulating school exhaust the energies of Nature by adding to the intensity of disease in their peculiar way, the narcotizing school do the same mischief by a similar neglect of the pathology of disease; and what in either case should be attacked by the lancet, cathartics, antiphlogistic alteratives, &c., is roused into greater immediate violence by tonics and stimulants, or indirectly by other morbific influences which appertain to the narcotics (§ 150, 151). Take, for example, the opinion of the able and distinguished London physician, Dr. Sigmond, who says that.

"Of all the different classes of medicine we possess, we may fairly consider the narcotics, skillfully, judiciously, and watchfully administered, the most important."—Sigmond's Lectures in London Lancet, 1836-7, p. 216.—And so, also, Pereira, § 960, a, p. 718.

The foregoing affirmation shuts out, of course, bloodletting, cathartics, all the important and numerous agents which I have grouped under the denomination of alteratives, as inferior, in therapeutics, to opi-

um, hyoscyamus, &c. (§ 854 bb, 857).—Note H p. 1117.

On the contrary, I shall have endeavored to show, in various parts of this work, that narcotics are but little more than humble auxiliaries to more important remedies, and then only in a comparatively small number of the cases of disease; or, that they are mere palliatives, giving a temporary ease by blunting sensibility, where death is probably

inevitable, and thus easing the sufferer out of existence.

891, d. That narcotics are extremely deficient in curative virtues should be sufficiently apparent from what has been already said of the uses to which they are constantly applied. But, even these intentions can be rarely well fulfilled by narcotics where much disease is We must then resort to the class of antiphlogistics for our great curative means; and, if the narcotics be summoned to their aid, it should be done with the greatest caution, or they may prove fatally morbific. We may exhibit opium, &c., for the relief of mere spasm of the stomach, to procure rest, &c., where no important acute disease is present. But he who should employ them to assuage the pain of pleuritis, enteritis, or any other active form of inflammation, and, in a general sense, of chronic forms, would either most seriously aggravate the disease, or destroy the patient (§ 150, 151).* Whenever, also, there is any affection of the head, or any tendency to cerebral disease, so great is the liability of narcotics to induce congestion of the brain, that they are totally inadmissible where that organ is increased in its susceptibilities (§ 137, d). And then let us consider their never-failing effect, in their ordinary doses of so injuriously modifying the action of the glandular organs, that the secretions of the whole, especially of that most important organ the liver, are more or less diminished; whereby Nature is obstructed in one of her greatest processes, natural and curative, and morbific nervous actions reflected upon all diseased parts, and upon the whole organism (§ 862, 863). Should this nervous influence excite in the skin a perspirable action, it is not of a salubrious nature; and here, again, we see demon-

* There would be as much propriety in treating pleuritis as peritonitis by the enormous doses of morphia now in vogue for the latter affection.—1860.—Note H p. 1117.

strated the evils that arise from regarding the product and not the nature of the action upon which it depends (§ 512 b, 863 d, 902 g). Hence has arisen the pernicious custom of depending upon the compound powder of ipecacuanha as a principal curative means in the treatment of fever. The opium determines morbific nervous actions upon the glandular organs and nervous system; being scarcely modified for the better through its union with ipecacuanha, even in its greater

diaphoretic influence upon the nervous power.

S91, e. In respect to the modus operandi of narcotics, I shall now only lay down the proposition that these agents produce their salutary or their morbific effects like all other remedies, or all other causes of disease, and set forth the proof in other appropriate places (§ $891\frac{1}{2}$ k, 904, &c.). The principle involved is so perfectly in harmony with all physiological facts relative to the healthy state of the body, and supported by all the well-ascertained facts in medicine, that it enables us to comprehend how it is that ten drops of the tincture of opium administered by the stomach will afford more relief to one man than fifty drops will to another, or how the ten drops of laudanum may do more injury in the former case, than fifty will in the latter, where the conditions of disease are exactly alike, but where the doctrine which I have advanced expounds the difference in effects upon natural physiological differences and other attendant peculiarities, and, as for the rest, by the production of a sedative reflex nervous action corresponding with the existing susceptibilities (§ 227, 447, $891\frac{1}{2}$ g, k, 904).

The failure of narcotics to produce the same effects when applied to the trunk of a nerve as upon its expanded extremities is a prominent fact in humoralism, and has contributed largely to the doctrine of remedial effect by absorption. The fallacy of the whole philoso-

phy is indicated in other places (§ 826, d, &c.).

891, f. The effects of narcotics generally decrease, respectively, when frequently repeated, or when habitually employed at more distant intervals (§ 558, a). But the organic properties, as in their relation to all vital stimuli, whether remedial or morbific, maintain about their usual susceptibility to all narcotics except the one in use; and it is therefore often advantageous to change from one to another, or to employ two or more in combination (§ 150, 151, 650, 889 k). And here I may remark how a single fact proves that remedies operato upon the system at large by reflex actions of the nervous system.

We have hitherto seen that an admirable variety of virtues appertains to many of the different members of each group of remedies, by which they are extensively adapted to various pathological conditions that approximate each other, but which are marked by such differences that, were each group composed of only one or two agents, we should be constantly baffled in the treatment of disease (§ 889, k). And, how vastly, in this respect, has the Materia Medica been improved in recent times by simplifying certain substances of compound virtues, attended, also, with much excrementitious matter; as in the examples of many alkaloids, iodine, &c.! Opium, for instance, is generally inadmissible in inflammations, unless to moderate irritability of the intestine in muco-enteritis, or of the lungs in pneumonia, or after the disease as affecting some other parts shall have been subdued by bloodletting, cathartics, &c. But morphia may be very appropriate when opium itself would be detrimental (§ 863, d). If nei

ther, however, be admissible, we possess in hyoscyamus, or conium or lactucarium, or lupulin, or churrus, &c., substitutes which may be often employed with advantage. So, again, belladonna, aconite, stramonium, render, each one, their peculiar services in certain painful affections, or other conditions of disease, or subserve some purpose in surgery. As these last three, however, possess no soporific virtue, but lead to sleep by assuaging pain and irritability, they are included in my arrangement under the denomination of senso-paralysants.

891, g. The most extensively useful effect of narcotics is that of procuring sleep; so great is the tendency to wakefulness in diseases, and so pernicious is its presence. This, too, depends greatly upon age; children requiring a great amount of sleep, while four or six hours will commonly answer for manhood and more advanced age. This is for disease. Rather more than the maximum is wanted in health. The law of adaptation comes, here, into operation, in morbid states, as with all things else (§ 137, 847 g, 848, 859, 863 d, 870 aa).

But, before the administration of narcotics for the purpose of procuring sleep, we should look well to the cause of the wakefulness; for the loss of blood, or a cathartic, or an emetic, or greater abstinence from food, &c., may be the appropriate means. When, however, narcotics are adapted their effect is peculiarly happy, not only in relieving and aiding Nature, but in promoting the operation of other reme-

dies (§ 137 d, 150).

891, h. We are often required to witness an obstinate wakefulness arising more from anxiety, or other affections of the mind, than from the disease itself; and when the day comes, the first glance of the eye upon the sunken or ghastly features of the patient may awaken apprehensions for which there is no just foundation. Now let the window-shutters be closed, exclude all unnecessary attendants, let the nurse be seated quietly in a chair, lay aside medicine and even food, take down the bed-curtains, ventilate the room, but not from a window that may throw a blast upon the patient, graduate the bed-clothes to his sensations, moderate or put out the fire, and if the patient have not rested when night comes on again, give him a suitable narcotic, keep all things quiet, and, at our morning call, we shall be likely to understand the reason why narcotics are so improperly administered when wakefulness arises from profound disease, perhaps of the brain, or when sleep is ample, but pain and suffering call for a relief that narcotics may not yield. It is the delightful effect of these agents, in the case which I have just supposed, and where preliminary means for tranquilizing the system have been adopted, that often leads the inattentive observer of the pathology of disease to their indiscriminate use: and his blindness is frequently such, and so great may be the quiet and insensibility which the narcotics produce, that the patient may drop into the grave without raising the suspicion that he was doomed by the treacherous remedy.

What I have just said of quiet, darkness, &c., are exceedingly important auxiliaries to soporifics, and should be carefully directed. They are causes, too, which should awaken attention to the modus operandi of active remedies, whereby the necessity of the latter will be greatly diminished. Choose, also, the night, when possible, for the exhibition of soporifics; not only on account of its greater stillness than the day, but because this is the natural time for sleep (§ 137, e).

891, i. The next great use of narcotics, in an absolute remedial sense, relates to their power of diminishing the *irritability* of disease; whether local or general, and thus aiding nature (δ 188, 905 b).

Irritability is augmented in inflammations, and it may be important to allay it by narcotics; not only to enable Nature to take on the cure, but to prevent the undue action of exciting causes (§ 137 d, 150, 645 c, 855). Thus, it may be very useful to exhibit morphia in pneumonia, after bloodletting; by which the cough may be more immediately assuaged than by the loss of blood. But narcotic means are more admissible, and far more useful in inflammations of the intestinal mucous tissue than of any other organ. Here, too, in various states of the alimentary canal, narcotics may often precede advantageously the administration of cathartics, or be associated with them; and, in a general sense, hyoscyamus is by far the best. In this case we lessen the irritability of the intestinal mucous tissue, and thus prevent the cathartic from doing mischief to the part (§ 889, k). So, also, in dysentery opiates are often given to allay the irritability of the part inflamed; even when no other internal remedy may be employed. Or, it may be to prevent any irritation from small doses of ipecacuanha, or calomel, &c. But when opiates are employed in such affections, the doses should be small, and repeated if necessary. Larger ones prove morbific. In serous inflammation of the bowels, on the other hand, they are entirely inadmissible (§ 137, b, &c.). But, it not unfrequently happens, that active inflammation seated in some circumscribed part of the intestinal mucous tissue induces spasmodic action in the contiguous muscular portion, which cathartics never fail to aggravate. In these cases a moderate dose of opium may relieve the spasm, and result in free dejections, by imparting a sedative influence to that reflex nervous action which occasions the spasm (§ $891\frac{1}{2} k$).

Nevertheless, opium should be always cautiously exhibited in all cases of the foregoing nature; but, with this reservation, they are likely to prove highly salutary in very many instances. But it is in all such instances only a subordinate agent; and it will be often far better to accomplish our purpose of obviating the apprehended bad effects of a cathartic, or any other remedy that may be likely to irritate the intestinal mucous tissue, by the general or local abstraction of blood, or by vesicating the abdomen (§ 890 b, 1058 f).—Note Gg.

It should be now said that puerperal peritonitis is sometimes treated successfully by opium given to full narcotization, though recovery is then as slow as seldom. The same has been more doubtfully affirmed of intestinal peritonitis. Irritability is so thoroughly subdued in the successful cases that it ceases to be morbidly excited by the blood, and the inflammation yields in consequence. Greater exceptions may be seen in § 756. The practice is empyrical (§ 1005 a-g).—Notes E H.

891, k. Next in order comes pain, depending on exalted or morbid sensibility. This might appear to call more frequently and imperiously for narcotics than wakefulness or the irritability of disease. But it is otherwise; though it is for the relief of pain that narcotics are most abused, and where they do their greatest injury. Whether they will be now beneficial will depend upon the cause of the pain, its seat, and other circumstances. If owing to active inflammation, they will be likely to aggravate the disease in most parts, but not in all. And here we learn the vast importance of a critical knowledge of the special vital endowments of the different tissues, and of a studious reference

to the seat of disease, as well as a critical examination of the attend ant symptoms, since the pain of mucous and serous inflammation of the intestine may be exactly the same, and opiates curative in the former, but certainly fatal in the latter (§ 133, &c., 150, 685, 686). Here, too, in the mucous tissue, they accomplish the double purpose of reducing irritability as well as sensibility (§ 150, 188, 194). In the other case, or that of serous inflammation of all parts, if they render sensibility obtuse, they do not often fail to injuriously modify the irritability of the part, and thus aggravate the disease. In the same general sense, also, opiates are more or less suited to inflammatory

states of the whole mucous system.

891, l. But, the great agent for the relief of pain attendant on active inflammation of any tissue is bloodletting; and this, particularly, when the disease affects any great vital organ. In a general sense, also, the less important the part the safer will narcotics be in inflammatory affections, whether acute or chronic; though, in these cases, care should be taken that they are not contra-indicated by obscure conditions of disease in the complex and great organs of life (§ 150, 689 l, 863 d). And here it is well to remark, that the organs most important to life are far from being most liable to pain. This is true of the lungs in pneumonia; and the liver, also, is but little subject to pain in any of its diseases, while the pleura, or peritoneum, or thecal membranes, the ligaments, &c., are never much inflamed without great attendant suffering. The urinary and generative organs are liable to very painful affections; and here, most happily, narcotics are very often admissible in their acute inflammatory diseases. So, also, they afford immense temporary relief in pain of the stone. They operate like a charm in cramp of the stomach, and in the suffering attendant on the passage of a gall-stone along the ductus choledocus. In these last cases the narcotic is directly curative by relieving spasm.

When pain attends chronic affections narcotics may be administered with less hesitation; but still with a careful reference to the seat and nature of the disease. They are of the greatest value, as palliatives, in the pain of cancerous affections, and generally for the suffering attendant on the chronic maladies of most parts that have not strong

sympathetic relations to important organs (§ 725, 859 b).

891, m. It may be said, in connection with the foregoing subject, that pain is very rarely a cause of disease, but may increase the force of such as may be present. But, even in these cases the aggravation of disease is owing more to the general disturbance inflicted, and to privation of sleep, than to any direct influences upon the part affected. Great suffering may exist without disturbing even the action of the heart, if the subject be firm of endurance. If the general circulation be disturbed as the apparent consequence of pain, it is mental emotion, not the pain, which produces the phenomenon (§ 167 f, note). Indeed, the true philosophy of life conducts us to the above conclusion, since the property upon which pain depends is not interested in the organic functions (§ 194, &c.). In the foregoing manner, or through the medium of the various mental emotions it produces, pain may aggravate or develop an attack of disease; and it is through the medium of the cerebro-spinal axis that it increases disease without the intervention of the passions, that is, by alterative reflex nervous action.

The power of endurance, and, therefore, the degrees of injury which

pain may inflict, depend greatly upon temperament, and the general condition of the constitution as arising from disease, habits, culture of mind, &c., and these contingencies affect, also, the susceptibility of the vital states. Much, too, will depend upon the kind of pain; and the kind, also, has its important influence in directing the treatment.

891, n. Owing to the prevalence of sympathies, the patient is often liable to be deceived as to the true seat of pain; and an inattentive or ignorant physician may be thus led into the greatest mistakes (§ 526 d, 891½ b). Diseases of the liver, for example, give rise to pain in the right shoulder, which opium may relieve, while it would aggravate the hepatic affection. Or, if he apply a blister, or other agents, to the shoulder, they will be useless. But, if placed over the seat of the liver, they will be more or less likely to relieve the remote sympathetic affection. This, also, enlightens us as to the importance of addressing our remedies, in all cases, mainly to the organs upon which sympathetic developments depend, and where they may remain under the in fluence of the primary affection (§ 689 l, 905).

891, o. We see, therefore, that blisters are among the great means of assuaging pain; but, like bloodletting, they operate in a very different manner from narcotics, though by reflex nervous actions.

There are, also, other agents not of the class of narcotics, which are remarkable for their control over the pain of particular modifications of inflammation, such as colchicum, guaiacum, &c. (§ 892 b, c,).

Hence we see, more and more, the uncertainty of pain as a guide to treatment, and that our remedies should be mainly determined by other considerations. Nor will I neglect the opportunity of saying how deeply all this subject relative to pain, wakefulness, &c., and the counteracting influences of the narcotics, should impress us with the futility of the chemical and physical philosophy of natural and morbid processes. From what we have seen, too, of the great variety of means by which pain may be assuaged, we come to an unhesitating conclusion as to the modus operandi of narcotics.

891, p. There is one agent not yet mentioned, which is often very remarkable for the relief which it affords in tranquilizing restlessness, allaying pain, and in procuring sleep; while it has also the great advantage of being generally free from objection. This is the warm bath; or analogous means in the form of warm fomentations and poultices. By these means intestinal pains, strangury, the intense suffering from sprains, painful menstruation, &c., are frequently dissipated at once. Again, refreshing sleep may be often induced by the warm bath when narcotics fail, or would be injurious (§ 150, 863 d). These agents are also curative in a direct manner; but variously so, according to the nature of the affection and the degree of heat employed. The bath at 105° or 110° F. frequently, perhaps daily applied, establishes such impressions upon the skin that highly salutary influences are often reflected upon some chronic forms of hepatic and intestinal disease, through the communicating sensitive and motor nerves.

As farther illustrative of the remedial nature of narcotics in relieving pain, and as contributing to many general objects in the philosophy of life, I may advert to the manner in which certain affections of the mind arrest intense suffering, remove wakefulness, &c. This is strikingly shown in the sudden subsidence of toothache when the dentist is expected, and in the relief which follows the exercise of

charms, &c. Certain sounds, also, by awakening agreeable emotions, produce similar results; as variously observed in the effects of music, the monotonous bubbling of the brook, &c.; and here the direct nervous influence illustrates the reflex of narcotics (§ 844).

891, q. Narcotics are generally directly sedative, though there is sometimes a temporary excitement of the general circulation. But, their great effect, and which is positively conclusive of their sedative action, consists in lessening irritability and sensibility in a direct manner. Nevertheless, opium is considered by many as the most powerful stimulant; which shows the importance of correct views in the

philosophy of life (§ 1057).

891, r. Narcotics generally produce their effects with rapidity, so that when their repetition is indicated for immediate purposes, the intervening time need not be long. And this leads me to advert to the remarkable manner in which pain often counteracts the sedative effect of narcotics, and enables the patient to bear a quantity that would be fatal in health. The solution of this problem is even beyond the compass of the physiologist; nearly as much so as that of sleep (\S 137 e, 150, 151, 175 e, 500 n).

Certain special affections of the nervous system also counteract the usual effects of narcotics in an astonishing manner; as seen in delirium of drunkenness, which excites an irritating nervous action.

891, s. Finally, habit, in respect to the use of narcotics, is very remarkable. Instances are authenticated in which the habitual use of opium has enabled individuals to carry it to the extent, daily, of more than three hundred grains. Solidism and vitalism point to correspondence between the general results and the amount of impression upon the stomach for an interpretation of the philosophy (§ 841).*

ANTISPASMODICS.

 $891\frac{1}{2}$, a. Two principal objects are contemplated in rendering the antispasmodics a subject of consideration. First, to aid in illustrating the philosophy which concerns the nervous power; and, secondly, to

indicate their misapplication in many conditions of disease.

 $891\frac{1}{2}$, b. The group of antispasmodics embraces all the narcotics, and regards them in the special acceptation which it is my present purpose to consider. As the term implies, they are employed for the relief of spasm, and, mostly, of the voluntary muscles. Now these agents are very commonly applied for the relief of the symptom, and with too little reference to the fundamental cause. Thus, Dr. Paris says that "Spasm may arise from excessive irritability, as from teething, wounds, worms, &c., in which case a narcotic would prove beneficial" (§ 526 d, 676 b, 891 n). I have taken this illustration because it is quoted by others as a good example of spasm where the narcotic antispasmodics may be properly employed. But, to my mind, all the conditions which are here stated very rarely admit of relief from narcotics, and are often aggravated by them. The spasm imputed to teething may depend upon a variety of pathological causes, however the irritation of the gums be a concurring cause. If it be due alone to dentition, lancing the gums is the remedy. If to intestinal disease which is maintained by teething, the remedies are then the foregoing and others of greater importance relative to the abdominal affection, such as calomel, castor oil, warm fomentations to the abdomen, &c. * See NOTE H p. 1117.

If narcotics be now employed, it is for the purpose of allaying intestinal irritability, and not at all with a view to their direct action on the cerebro-spinal system. As to spasm from wounds, the narcotics have been most extensively tried and abandoned as useless, excepting where they are slight; and then, more relief may be procured by a warm poultice applied to the wound. If worms be the cause, we ought surely to look for the remedies among the anthelmintics (§ 150,

526 d, 891 n, 859 b, 863 d).

891½, c. Antispasmodics have been largely employed in hysteria. But here they have been almost as fruitless as in the spasms of children; though, perhaps, not so detrimental. Hysteria, in numerous instances, is so dependent on some uterine derangement, and this condition so often consequent on visceral disease of the abdomen, that the treatment should be, in such cases, of quite a compound nature, but in which antispasmodics can take no useful part. An emetic, however, in a general sense, will afford temporary relief, which it accomplishes in part by modifying the several conditions of disease, and in part through influences which are called into operation in suspending a paroxysm of spasmodic asthma, and hiccough, as explained in section 514, c, where the philosophy rests upon reflex nervous action.*

891½, d. Chorca is another complaint in which antispasmodics have been extensively employed, and with as little reference to the cause of the symptom. They have, therefore, failed, or have left the patient for the worse. Abdominal disease being at the foundation, the remedies should consist of cathartics, a well-regulated diet, exercise, and

change of air (\S 150, \S 63 d).

891½, c. But, worse than all, antispasmodics have been in high repute for epilepsy; notwithstanding their universal failure to afford any relief. The disease, however, is attended by spasm, and the symptom, as in the other affections, has been taken for the disease, and no small amount of suffering and death have been accordingly inflicted by antispasmodics. In many cases this affection depends, immediately, upon cerebral congestion; and then bloodletting, mostly, is the proper remedy. At other times it is owing to a transient sympathy of the brain with an overloaded stomach; when a mild emetic is the sure antispasmodic. In other cases the sympathetic disturbance of the brain depends upon profound disease of the liver and other abdominal organs; and here, cathartics of calomel, &c., and doubtless bloodletting also, are the appropriate means. Again, it depends upon organic disease of the brain, or on a spicula of bone projecting from the dura mater, or on depression of some part of the cranium.

The foregoing are almost all the causes of epilepsy; from which it results that antispasmodics should have no place among the remedies for this affection (§ 150, 847 g 848, 859, 863 d, 870 aa, 1058 v).

891½, f. Congestive asthma, the usual form of the disease, has had its full share of the antispasmodics, and, of course, with as little bene fit as they have yielded to the preceding affections. They are more or less appropriate, however, to the rare form of spasmodic asthma; but here an emetic is often better, or a pipe of stramonium leaves may answer (§ 514, c). But congestive asthma depends upon something more than simple irritation of the nervous centres. There is a highly-injected state of the venous system of the lungs, consequent on disease of the abdominal viscera, involves many important organs, and

^{*} See NOTE Cc p. 1132.

calls imperatively for blood-letting, and cathartics (§ 150, 786, &c.,

847 g, 848, 859 b, 863 d, 870 aa).

891½, g. We have thus seen various examples in which reflex actions originate either in sensitive fibres of cerebro-spinal nerves and terminate in motor sympathetic fibres or vice versa, and direct nervous action originating in the brain or spinal cord and terminating in motor fibres of the sympathetic system (§ 111–113, and references there, 488½, 893 a).

 $891\frac{1}{2}$, h. It appears, also, that the true narcotics must be commonly

injurious in most of the affections which give rise to spasms.

 $891\frac{1}{2}$, i. But there are some agents which are mostly antispasmodic, in their relation to the nervous system, such as asafætida, musk, valerian, &c. These agents are known as the true antispasmodics, although opium greatly transcends the whole in its virtue of arresting spasm. But those of simpler virtues are very circumscribed in their morbific relations to the brain and to other organs, and exert but little effect as therapeutical agents (§ 150). This leads me to consider the re-

maining object of the present inquiry (§ $891\frac{1}{2}$, a).

 $891\frac{1}{2}$, k. No one can mistake the immediate bearing of the whole of this subject upon the general philosophy which concerns the modus operandi of remedial and morbific agents, while the function of respiration, and other natural processes, display the physiological laws under which the former are directed (§ 462-475, 495-534, 639 a). Although, therefore, the phenomena of spasm form so luminous a guide through the whole labyrinth of sympathy, and impart a peculiar interest to the discovery of Sir C. Bell in relation to the different orders of nerves (§ 462-470, 476 b), we need not be long detained in making

the contemplated exposition. In the first place, then, we

In the first place, then, we observe that the irritation of the nervous centres may be either direct, as in severe forms of epilepsy (§ 891½, e), or indirect, as in the more compound and ordinary reflex nervous influences (§ 227, 230, 500). In the former case the nervous power is developed in a direct manner, either in virtue of some disease affecting the nervous centres, or by some direct mechanical irritation, as in depressions of the skull-bone, projecting spiculæ of bone, and extravasated blood (§ 476-494). In the latter case the primary irritation is in a remote part, as in the gums, or intestinal canal, &c ($\S 891\frac{1}{2}$, a). In this instance the impression is transmitted through sensitive nerves to the nervous centres, where it operates as an exciting cause of the nervous power, and is exactly equivalent to the direct irritation of those centres; as observed in the former case. The residue of the process then becomes alike in both the cases. That is to say, the nervous power is reflected through motor nerves, or motor fibres of compound nerves, upon the affected muscles, and thus are they thrown into spasmodic action (§ 230, 233, 500, $893\frac{1}{2}$.)

Such, again, are all the elements; and since they are now in operation in their morbid aspect, we have the plainest demonstration that

the whole process depends upon natural physiological laws.

And now, briefly, for the opposing or curative influences. We have seen that when the simple antispasmodics arrest the movements, they institute only mild impressions upon the nervous centres; but they must necessarily modify the nervous power in its very nature, or they could not arrest the movements of the muscles; since it is the nervous power which now operates, and upon exactly the same mus-

cles in which it had developed the spasmodic action.* In one case, therefore, it acts as a stimulant, in the other as a sedative. More or less, however, is due to a mere suppression of the exciting nervous The same results obtain, also, when the narcotics operate in simply removing spasm. But these are agents which embrace other virtues that are very apt to prove morbific (§ 891, d), and their morbific impression may be transmitted from the stomach to the nervous centres, especially on account of their specific relation to the nervous system (§ 137, c), without first engendering or increasing disease in the stomach or other parts (§ 502, c), or, there may happen along with this a direct morbid change in the condition of the stomach (§ 502, c). or indirectly, through the increased morbid change in the nervous power, in other parts. These new conditions of disease may aggravate the spasmodic affection; since the nervous power is not rendered sedative to the affected muscles (§ 150, 228 b-232, 233 $\frac{3}{4}$); or, on the other hand, the morbid change may be of such a nature as to break up the special condition of the nervous power which gives rise to the spasm, and thus put an end to that part of the malady, although there ensue a very aggravated state of disease (§ 890, 900, 901, &c.). Thus we see presented the compound aspect of a remedial agent bringing about relief to one part of disease, or removing one symptom, and simultaneously aggravating or inducing disease in other parts, and increasing all other symptoms. The principle is distinctly the same, throughout, as when the narcotics, or simple antispasmodics, establish that change which results only in the removal of spasm. There is, therefore, presented in the examples before us, as a general ground for the interpretation of morbific and remedial agents, the union of the physiological, morbific, and remedial processes (§ 903, 984 b).

From the foregoing facts and philosophy we might reason safely to the modus operandi of all other remedial and morbific agents, especially in connection with the natural processes of sympathy (§ 500), had we not about the same amount of concurring proof in the mani-

festations of every other cause.

CINCHONA, AND ITS ALKALOIDS.

Tuto, cito, et jucunde.

892, a. As an interesting incident in the history of this extraordinary agent, it may be said that the Peruvian bark was not introduced into Europe till the year 1640, or more than one hundred years after the full conquest of Peru; which is abundantly conclusive that all the alleged connections of the savages, lions, and vultures, which continue to appear in works on the Materia Medica, are wholly fabulous. was not, however, till a century afterward, or in 1738, that the plant became known to naturalists, through Condamine, the French savant. His account of the tree appeared in the Memoirs of the French Academy, along with the story about the lions. Condamine says that the Countess del Cinchon, wife of the Viceroy of Peru, carried the bark to Europe in 1640; from which circumstance, and from her previous connection with the introduction of the bark into use, as stated by Condamine, Linnæus immortalized her name. The countess brought the bark into use in Peru by a first experiment upon herself, at the suggestion of the Corregidor of Loxa. She then transferred its patronage to the Jesuits; when the bark dropped the name of the "Count-

* Shown also by certain external applications, as when camphor or ice applied to the skin relieves instantly the spasms in malignant cholera (p. 838, § 1057½).

ess' powder," and became known as the "Jesuits' bark." It would be an entertaining inquiry to follow the history of cinchona after its introduction into Europe. No article of the Materia Medica has employed so extensively the pens of medical philosophers, and under every aspect of praise and condemnation, and of angry controversy; and next to this, that now universal luxury of man, the nicotiana tabacum. Before the time of the alkaloids, Von Bergen published the names of more than six hundred authors whose writings he had consulted on the subject of the Peruvian bark, and refers to eight hundred distinct treatises upon this remedy. Subsequently to that period, the discovery of the cinchona alkaloids, and their application as therapeutical agents, have given rise to so vast an accumulation of books, pamphlets, and memoirs, that the writings upon this single article of the Materia Medica would, alone, form a library of very imposing dimensions. And yet do I find myself at the threshold of another paragraph upon what should seem so completely exhausted. I shall therefore endeavor to turn myself upon that track which has been least pursued, and which, as in many other cases, is too often abandoned,—the path of Nature.

The bark, having been early carried from Spain into Italy, it may be well supposed that a country so liable to intermittents, and those, too, of the most formidable character, would soon illustrate the virtues of this extraordinary febrifuge, and enlist in its favor the most powerful patronage. About this time, however, it was called to encounter one of those checks which it repeatedly afterward underwent with less disaster, and which will remind us of what has befallen the philosophy of medicine in the laboratory of a German chemist. I shall therefore state it, in the hope, at least, that it may go with the rest in promoting independent habits of observation (§ 349 d, 350, 350½).

The commendations which the bark received from the priesthood, and the popular appellation of the "Jesuits' bark," were not sufficient to establish its success in countries less scourged by malaria than the Peninsula; for even in Spain the physicians were either disposed to reject the remedy, or to meet it with opposition. But, its demonstrations were such in the Italian climate, that Pope Innocent the Tenth made it the subject of a papal communication to the Church, and co-operated with the Italian physicians by directing the publication of their report; in which the curative virtues of the bark were set forth with all the confidence that has been warranted by subsequent experience.

The medical document which was thus promulgated was called the "Schedula Romana," and contained directions for administering the bark as to time, quantity, &c.; the established dose being two drachms

of the powder.

This Schedula soon became a target for those who had been hostile to the bark; and the warfare was begun by one who had professed to have entertained prepossessions in its favor. This individual, whose name was Chifletus, was prompted in his opposition to the bark by its partial failure in a case where it was important for the physician to have obtained more complete success. A relapse, however, ensuing at the end of a month, the chagrin of the physician led him to denounce the remedy in such violent terms, that it lost, at once, many of its firm friends, and rekindled the animosity of its opponents

Chifletus boldly assumed that all the Roman and other encomiums were mere pretense, and that the bark was not only useless as a remedy for fever, but absolutely pernicious, and should be utterly proscribed by the profession. He challenged any well-authenticated cases of cure; and by this arrogant style he attracted the attention of no small part of Europe. The credulous came to believe his assertions, and the evil-disposed united in a crusade against the tenant of the Andes. Chifletus was hailed as a great public benefactor, as "the Reformer" of the day, in having relieved the world of a scourge. His publication was reprinted in the languages of different European countries; and, for awhile, the whole profession appeared to acquiesce in the justice of the decision.

Nor was this condemned article ultimately rescued from the trammels of ignorance and prejudice by its proper guardians; but by a learned Jesuit, who once more bore it aloft by unequivocal proof of its extraordinary control over the great bane of Italy. From that time, opposition became more and more feeble, and the merits of the

remedy gradually established.

But, this is only a passage in the early history of the Peruvian bark. It was not, like the tobacco, required to encounter the edicts of despots, though it equally underwent the ordeal of a fierce disputation; and it is scarcely possible for us, who now contemplate these two remarkable members of the vegetable kingdom with the calm indifference of long and universal experience, to appreciate the uncertainty in which their virtues were held, or the angry and vindictive reproach

to which that uncertainty gave rise.

We see, also, in the nature of the hostility which was for awhile waged by a great part of the profession against this invaluable remedial agent, and in the very face of its triumphant success, a disposition to trample upon the best interests of society, where it may seem expedient to bow to the dictates of a despotic writer, or where professional pride, or cunning jealousy, or malevolent envy, may hope for gain. Nor can we fail to observe in this extraordinary and almost universal denunciation of the Peruvian bark, as a curse which was scarcely exceeded by pestilence, a striking parallel with the furious opposition which bloodletting has been required to encounter.

It is also an interesting, as well as instructive, coincidence, that while Sydenham was storming the prejudices against the remedium principale in the treatment of inflammations and fevers, he was also employed in combating the opposition to the bark, which had become very general in England. He triumphantly set forth the advantages of the former, and compelled his obstinate cotemporaries to acknowledge the healing virtues of the Peruvian febrifuge. But, to the Pontine marshes of Italy we may refer the stability which was first bestowed upon the bark. Here were perpetually emitted the seeds of intermittents, which were now, for the first time, controlled extensively by the all-potent drug.—Notes F H K pp. 1114, 1117, 1119.

892, aa. In my Arrangement of the Materia Medica, I have grouped together, in the order of their therapeutical value, many agents which are peculiarly appropriate to intermitting forms of disease, and, into this group no other remedies are admitted. They possess, therefore, what are commonly denominated specific virtues in relation to the diseases to which the group refers. This, indeed, may be more

or less affirmed of all the other groups, excepting those of a common antiphlogistic nature. It is not, therefore, to be inferred, when the remedies for any given character of disease are specifically indicated, that there may not be others that are more or less appropriate, but which are not included in the group before us (§ 137 d, 150). tics, even, are liable to this qualification; since, without previous bloodletting they will often aggravate disease. But, after applying the former remedy the cathartic may cease to be necessary. The loss of blood has accomplished all that was contemplated from the internal agent; but blood-letting cannot be arranged among the cathartics. In certain conditions of amenorrhoea it may be evident that guaiacum will establish menstruation after blood-letting or a purgative, but would be injurious without, or either of the last may be sufficient. Now, the same remarks are precisely applicable to the group of anti-periodics, unless it be that the virtues of these remedies have a remarkable bearing upon the remote causes of intermittents ($\S 650, 652 c, 653, 662, 675$).

892, b. It is the prevailing doctrine that cinchona, arsenic, and other anti-periodics operate by either neutralizing some imaginary poison, or by forming chemical combinations with the tissues of the body, and thus transmuting them into their normal conditions; while there are a remaining few who ascribe the results to molecular changes induced by a tonic or astringent principle, as in tanning (§ 350, nos. 41, 42, 487 h, $569, 851 \, a, 890 \, a, 892 \frac{1}{4} \, i$). On the contrary, I endeavor to show that these remedies in subduing special forms of inflammation and fever operate upon the same principle as loss of blood, cathartics, and antimonials, in the common forms, and therefore as antiphlogistics (§ 756 a, b). Excepting loss of blood and the antimonials, the remedies which are appropriate in a general sense to inflammations and fevers will often prove morbific in some of the pathological phases of the common forms of those diseases. Cathartics are comparatively of little use, and often injurious, in pneumonia, pleuritis, enteritis, phrenitis, &c., without antecedent loss of blood; and this is still truer of vesicants, which may ultimately render important service in those diseases. But there is a large class of inflammations which deviate from the common form, known as specific (\$ 648, 653, 721-722). Here, however, the same principle obtains, and is corroborated by a greater variety in the means that may be suitable to the special pathological conditions. Intermitting inflammation and intermitting fever are specific forms of inflammation and fever, and are so far bent from the common forms as to be benefited, in connection with the general antiphlogistics, by many heterogeneous remedies of special virtues, but which will aggravate the common forms of those diseases. And just so of chronic rheumatism, for which colchicum, and guaiacum, and veratria, and other acrid and miscellaneous substances are special remedies, but which will aggravate not only the common form of inflammation but even acute rheumatism. Blood-letting, however, and tartarized antimony, are the main remedies for intermitting inflammation and acute rheumatism, and generally the best for the chronic forms. It would be, therefore, equally necessary to deny that loss of blood and antimonials act as antiphlogistics, in the vital acceptation, as the foregoing specific remedies, and to assume that the entire medley, indiscriminately employed, lead to a common result in the cases supposed by some common neutralizing or chemical process (\$ 350, nos. 41, 42)! As well might it be assumed that any of the

remedies for intermittents will unite and form an identical compound. The mercurials will oftener overcome syphilitic inflammation than any other form, and oftener than any thing else. But iodine, and sarsaparilla, and a non-stimulating diet, and frequently loss of blood, are very good remedies. And so of scrofula, in which the general antiphlogistics are often necessary, but mainly sudsidiary to iodine and bromine, while the latter never fail to aggravate the common form of inflammation (§ $851\ a,\ 863\ d,\ 892\frac{1}{2}\ v,\ 892\frac{1}{5}\ g,\ 896-900,\ 904\ c,\ 905\frac{3}{4},\ 951\ c,\ 1065$).

Having thus divested this plain affair of the mystery which has been thrown around it, and seeing clearly the simple principles through which all remedial effects are produced, we may bring the philosophy with no little aid to our experience in the treatment not only of intermittents, but of all other diseases.—Notes K L pp. 1119, 1120.*

892, c. The considerations to which I have now referred, along with what is known of the peculiarities that appertain to the virtues of every remedy, and how those virtues may prove morbific as well as salutary, enable us to understand the favorable and unfavorable relations which cinchona, or arsenic, may bear to the different stages of a paroxysm of intermittent fever, when to apply the remedies and when to withhold them, how they may aggravate any coexisting local congestion or inflammation, or how, from our knowledge also of the modifying effects of the remote causes, these agents may, at other times, arrest the local as well as the general disease, or how other agents, like bloodletting, will place the unfavorable states in a favorable way for the action of the tonic febrifuge (§ 150, 675, 847 g, 848, 857, 859, 863 d, 870 aa). We learn, also, from the same considerations, and from what is set forth in section 904, d, that no remedies can be properly regarded as specifics, neither cinchona, arsenic, &c.; since, from the vast variety and contradictory nature of the means by which intermittents may be arrested, we may clearly perceive that no one of these causes exerts what is understood by specific effect. The several means, however, arrest the disease; and they do it by instituting such changes in the diseased conditions as place them in the way of restorative changes (§ 672). Each one, however, determines changes according to its own special virtues, and in no other sense are they specifics. So far, then, they are exactly on a par with any other remedy, and with every cause of disease (§ 52, 150, 151, 650, $892\frac{2}{3}$ d). But, this peculiarity of virtues is more strongly pronounced in some things than in others, and is seen remarkably in cinchona; as in its profoundly morbific effect during the hot stage of the febrile paroxysm, and its equally curative demonstration during the period of intermission. Here, too, I may again say that its mode of operating at these successive stages of one and the same disease is distinctly seen to be of a common nature (§ 675, 891½ k). Here we have not only a consistent philosophy throughout, but, also, in that philosophy and the attendant facts a fountain for many practical conclusions; such, for instance, as the importance of bringing about, in a general sense, distinct intermissions before resorting to what are emphatically denominated remedies for intermittents; and that it would be improper, in a general sense, to employ the agents now under consideration, in remittent fever, or, at most, not till the febrile action has been modified by direct antiphlogistic means (§ 150, 847 g, 848, 857, 859 b. 870 aa, 1059.—See Modus operandi of Cinchona, p. 677, § 904 d)

Nor may we begin, precipitately, the treatment of intermittents by cinchona, nor by any agents of the present group, simply because it is an intermittent, and there happens to exist that suspension of febrile action which is known as the period of intermission (§ 675, 890, d, There may be present some local congestion or inflammation that may demand the abstraction of blood; and the general condition of things will rarely fail of requiring a cathartic, at least. But, it often happens before any preliminary treatment may have been adopted, that an intermission is pretty strongly pronounced, and yet that the intensity of the febrile condition is such as to raise apprehensions that the patient may be destroyed by the violence of the next These are frequently cases for grave deliberation, whether we shall abstract blood, or administer a purgative, or an emetic, or proceed at once to the employment of bark. If no important local disease be present, some eight to fifteen grains of calomel should be giv en, followed soon by an appropriate dose of castor oil, and, in the mean time, the sulphate of quinia should be exhibited till the next paroxysm takes place. It will not do to prostrate the system in these cases by an emetic. In the way now suggested, however, we may stay the violence of the approaching shock. Will chemistry explain?

On the other hand, if there be any serious amount of congestion in the liver, or inflammation of the intestinal mucous tissue, as commonly happens with the liver especially, we shall accomplish nothing by this early use of the bark, in these concentrated forms of fever. Either trust alone to the cathartic till after the next paroxysm, or bleed the patient also. There is no "debility" in the case. Keep the eye on the pathology. Nature may rise up at once under the lancet, when she would sink under an emetic, or the tonic virtue of the febrifuge (§ 150, 569 e, 576 e, 847 g, 848, 857, 859 b, 863 d, 870 aa, 961, 962).

892, d. Having brought the system into a condition for the administration of cinchona, or some of its preparations, we are next to ascertain which of the two methods should be adopted; for there are two

modes of treatment having essential differences.

One of these methods consists in making a very strong impression, at once, by a single blow, as it were, upon the diseased conditions, during the intermission, by the administration of a large dose of bark, or of quinia (as five or ten grains of the latter), and thus endeavoring to arrest the fever at once.

The other method is one of greater moderation; the remedy being exhibited in small quantities (as that of a grain of quinia), at intervals

of two to four hours throughout the intermission.

By the latter process the alterative action is more gradually exerted; so that the paroxysms may continue to recur an uncertain number of times, but with diminished intensity, till, at last, they disappear.

And now as to the relative advantages of the two methods. In the first place, we can readily understand, theoretically, that the precipitate course, by large doses, may exasperate any coexisting inflammation or venous congestion; and yet, from the difference in the pathology of fever and inflammation, the former condition may be overthrown.

We know, also, that it will not answer to arrest the fever suddenly by arsenious acid; because a large dose of that remedy may inflict a far greater evil than is constituted by the fever. Such, in fact, is the negative reason; for an excessive dose of arsenic may arrest the complaint at once. It is only, therefore, its liability in large doses to inflict other mischief that prompts its administration in small doses. And just so it may be with cinchona, or its alkaloids, and their salts. In the former case the morbific effects are strongly pronounced, and the agent is not prescribed at random. But, it is quite otherwise with the large doses of quinia. The attending venous congestions, which are very apt to be present (and far less frequently other forms of inflammation), may be increased and established without manifesting any striking phenomena to admonish a hasty practitioner of the mistakes he may have made (§ 790, 795 b, 798, 801, 806, 807, 811, 815, 816, 961–964, 967).

Now, experience shows exactly what theory, suggested by the true operation of remedies, rendered more or less probable. Experience, I say, shows that, though bark, and its alkaloids, in large doses, will often arrest intermittent fever suddenly, such doses are liable either to induce some congestion, especially of the liver or of the mucous tissue of the stomach, or will aggravate and establish some coexisting congestion; and thus, while the patient is, for the present, relieved of the fever (§ 904, d), he is dismissed with an insidious local complaint that not only renders him a permanent invalid (resulting often in indurated enlargements, § 803), but which local malady may, and often does, become, in a process of time, the exciting cause of another attack of fever; thus showing, also, that the predisposition to the constitutional disease remains, although the paroxysms, and therefore its absolute condition, were interrupted (§ 150, 560, 665, 666, 779, 904 d).

In other words, while we thus inflict a useful and sudden blow upon the fever, or general malady, through one virtue of the bark, we lay the foundation of a local disease, through the tonic virtue, in itself perpetually harassing, undermining the constitution, and not unfrequently so establishing the predisposition to fever, that the patient will continue to suffer returns of it from time to time during the residue of the brief period of life which an indiscreet practice not unfrequently allots to him. He is but "imperfectly cured," as Celsus has it; and these imperfect cures become the slow cause of those chronic enlargements of the liver and spleen for which iodine is especially beneficial. In respect to relapses, it is not infrequent that, when intermittents are suddenly stopped by a large dose of quinine the paroxysms return as soon as the patient begins to exercise much, or to take his ordinary food,—certainly with far greater frequency than when the case has been treated upon the moderate system (§ 847 g, 848, 857, 859 b, 870 aa, 878).—Notes K p. 1119, L p. 1120.

It is now interesting to remark that the plan of large medication is apt to be adopted by those practitioners who are least inclined to recognize bloodletting as of much importance among remedial agents, or do not see in the philosophy of disease any other elements than debility and something in the blood to be expelled or neutralized (§ 569, 960), and suppose that medicines do the whole work of cure (§ 853, 856).

On the other hand, when the gradually alterative process is pursued, the patient is not only about as expeditiously relieved of the fever, but, also, of his local congestions; for, Nature has now a chance to throw off these more obstinate affections (§ 904, d), which she is greatly disposed to do waile undergoing the gradual removal of the febrile

action; so only we do nothing to interfere with these local salutary efforts (§ 662). But, there is also the more important advantage resulting from the negative fact of not directly increasing, or actually

producing, congestions by the milder system of treatment.

According to this plan, certain other objects of the highest importance are not as likely to be overlooked as when its antagonist is brought into action. It presupposes a tolerable regard for the existing state of the pathological conditions before the treatment is begun, that care is taken that all congestions or inflammations of important organs are so far mitigated by bloodletting or cathartics, or by antimonial alteratives, and the intensity of the fever so far subdued by some one or more of those direct antiphlogistics, as shall render the tonic febrifuge not only safe, but speedily curative (§ 150, 151, 847 g, 848, 857, 859 b, 863 d, 870 aa); for speedy it will almost always be when its administration is proper, and the case continues to be judiciously treated. If the intermissions be not well marked, there probably remains some special burden of disease upon the stomach, or liver or other important organ, which should be yet farther mitigated before the use of the tonic febrifuge is begun; although, as already seen, it may be sometimes employed in cautious doses where the local inflammations and venous congestions have refused to yield to bloodletting, cathartics, antimonials, &c., and even now and then at rather advanced stages of the disease where the paroxysms run into each other (§ 662). In all such cases, however, we should move on with great circumspection; never employing the agent of tonic virtues till it become apparent that this form of fever, and its local complications, are not likely to surrender to the direct antiphlogistic means (§ 870 aa).

Among what may be considered the subordinate remedies, but which are truly among the most important, are perfect rest in bed, and a total privation of stimulating and solid food during the existence of the fever, whatever may be its prolongation. It is astonishing, I say, what an important agency these two negative remedies exert. Animal food, although it be fluid, will stimulate injuriously, or, if the food be in a solid form, it will irritate the stomach mechanically; while the erect posture, if long continued at least, proves in other ways an exciting cause. And then, as to all those things which so falsely pass under the denomination of refrigerants, such as the acid of lemons, oranges, &c., they never fail of so irritating the intestinal mucous tissue as to aggravate the symptoms which they are intended to assuage. A cathartic, or bloodletting, are the only things that deserve such a name, unless it be ice; and even in regard to ice itself, either of the first means may prove far more refrigerant to the organic being (§ 150, 151, 440 e, no. 14, 441 c, 442 b-e, 443 c, 447 c, d, 447 h,

 $447\frac{1}{2}f$, 863 d).

A proper want of attention to food, and fatigue from exercise, during convalescence, are the great causes of the relapses which take place after well-treated cases of intermittent fever. Almost any thing will arrest the paroxysms when applied under favorable circumstances. And just so it is on the other hand; almost any thing unduly applied will reproduce them while the predisposition is strong, as it commonly is for some time after their subsidence. Will chemistry explain?

892, e. In the quotidian form I commonly exhibit one grain, in so-

892, c. In the quotidian form 1 commonly exhibit one grain, in solution, of the sulphate of quinia every two or three hours during the

intermission. In many of the cases the patient does not suffer another paroxysm after the preliminary treatment and beginning the use of quinia; but, in a majority of instances he has another paroxysm, but of great comparative mildness. This, however, is almost invariably the last of the fever.

In the treatment of tertians, the intermission being longer, more time is allowed for producing the requisite impression by the quinia, and I therefore take no unnecessary risk of aggravating, or of producing any local forms of disease, but administer the sulphate of quinia in doses of one grain once in three or four hours; and I continue this regular exhibition of the remedy throughout the night. In a vast majority of these cases there has been no return of the paroxysm after beginning the use of the quinia—so only the fever have been a regular tertian, and the intermission well marked. But absolute rest, and a fluid, farinaceous diet, till there is a failure of the periodical return, are a sine qua non.

892, f. The various means which I have now stated as to the treatment of regular intermittents, with the exception of cinchona, are still more important in remittent and continued fevers; and their importance increases in the ratio of the intensity of any local inflammations and congestions of important organs. The former affection is here far more apt to spring up than in intermittent fever, especially in the continued form; while venous congestion is the predom-

inating condition in intermittents and remittents.

892, g. When the hot stage of an intermittent is unusually prolonged I have found it most useful to employ not more than half a grain of quinine at a dose; and, in remittents, of the most formidable nature, after repeated abstractions of blood, and the exhibition of cathartics, especially of calomel, and alterative doses of tartarized antimony, I have in the end resorted to the sulphate of quinia in the minute doses set forth in section 870 aa, and patients have been thus rescued from otherwise inevitable death.

Here, too, as in numerous other gradations of febrile action, especially where the constitutional affection is not subdued into a distinctly intermitting form, or where it remains complicated with declining inflammations, quinine may be brought to bear advantageously in small doses, by associating with it the minimum doses of tartarized antimony, when the former agent would be otherwise morbific. The antimony lessens irritability, subdues arterial action, and thus counteracts the stimulant virtue of the tonic febrifuge, while it also reaches more profoundly by its alterative virtue. For an opposite rectifying influence tonics may be sometimes brought usefully to the aid of antimony; especially where unsubdued chronic inflammations are kept up by prolonged indigestion. So, again, cathartics, especially the neutral salts, may be added to tonics with the same double intention; or. on the other hand, tonics may be combined with cathartics to counteract the prostrating influence of the latter.

892, h. On the Continent of Europe, and in many parts of the United States, ten grains of the sulphate of quinia at a dose is common; and this explains the reason why an impression has obtained that this compound is apt to irritate the stomach, or to produce purging. If its full effects in such quantities were farther analyzed and better appreciated we should also hear of them much more unfavorable reports.

892, i. The celebrated French writer, and admirable practitioner. Tissot, more than a century and a half ago, complained that the bark had suffered much in reputation from being employed in too small a quantity. The subject, in consequence, was submitted to the test of critical observation. The dose employed by himself, and which was about the same as sanctioned by the distinguished men of that age, was one drachm of the powdered bark. If the fever were of the tertian type he administered eight of these doses during the intermission, or a dose every three hours. For a quartan he prescribed the same dose, and at the same interval, so that, instead of an ounce, as in the tertian form, an ounce and a half would be taken during the period of intermission. "These doses," he says, "frequently prevent a repetition of the paroxysm." And this it would have done with greater success had it not been the usage of those days to enjoin exercise upon these patients, and even to allow them solid food during the intermission.

As to the quantity of bark, Tissot gave the maximum dose that was mostly employed. This was considered abundantly large. Tissot, indeed, observes that, "The frequent failures of the bark are owing to small doses. On such occasions the medicine is cried down and condemned as useless, when the disappointment is solely the fault of those

who do not employ it properly."

If we allow, therefore, the large proportion of one grain and a half of the alkaloids to one drachm of good bark, and that the febrifuge virtue of cinchona depends mostly upon these principles, we shall not have more than one grain at a dose in actual operation, on account of the nature of the compound. But, in a great proportion of the barks in common use there is not the quantity of one grain of the alkaloids in a drachm of the bark. The crown bark of Loxa (C. Condaminea), an excellent species, and mostly in use in Tissot's day, has less than half a grain of the alkaloids to each drachm. These facts are of great practical moment as it respects the important question now before us; as they come from some of the very best observers, men who would venture upon bloodletting whenever necessary, and who had the same question under consideration.—Notes K L pp. 1119, 1120.

In Tissot's time, however, there were many who employed excessive doses of the bark, and thus injured or destroyed their patients. And this, of course, was another reason why the bark was often in disrepute. The alkaloids, it is true, are rather less morbific; but not at all so in the ratio of the moderate and immoderate practice. The consequences, therefore, are the same now as represented by Tissot,

Morton. Torti, Sydenham, and others, in their times.

Be it also remembered, that they who are thus fearless of the cinchona alkaloids, and others who administer calomel by the table-spoonful in congestive fever, and tartar emetic in five to ten grain doses, repeated at short intervals, in the treatment of pneumonia, &c., are the very ones who most condemn the greatest, safest, and most speedy of all means for the cure of such affections. And just so, too, as in former times, the public, seeing the failure of their efforts with quinia, and other powerful internal agents, as is very natural with a class so entirely uninformed of the true merits of the case, run to an opposite extreme, and imbibe a belief that medicines are hazardous unless in such small doses as shall exert no effect whatever. The

confidence of the public being thus more or less impaired in the whole profession, there will not, of course, be wanting those who, as in Tissot's day, will take advantage of this false conclusion, and will, as in former times, employ cinchona, and other remedies, in such minute doses as will render no aid to Nature (§ 854 bb, 878, 894, mottoes).

892, k. The large medication by quinia may be traced up, in part, to the analogous use of tartarized antimony in Europe. But, while the treatment of intermittents by doses of five and ten grains of quinia has extended from Europe to America, we have not kept pace with its progress there. How far this practice has had its origin in physiological or pathological facts may appear from some of the results which have been affirmed by its advocates. Thus, the distinguished M. Piorry, having embraced the opinion of M. Louis that the enlarged and indurated spleen, a condition which often supervenes on neglected or badly-treated intermittents, is the cause of the fever, applied the treatment upon that hypothesis. Accordingly, we learn from M. Piorry the following results. In a patient, for example, affected with a quotidian, we are gravely told that,

"All the organs were HEALTHY, except the spleen, the length of which was seven inches and ten lines, breadth five inches and five

lines."

To this patient thirty grains of quinia were given at a dose, and in twenty minutes afterward the hypertrophied spleen was reduced more than one inch in its length and breadth, as ascertained by percussion; but which we may regard as physiologically impossible. Four days afterward, as the paroxysms still continued, M. Piorry gave this patient forty grains of the sulphate of quinia at a dose; and measured the spleen by percussion in twenty minutes afterward, and found it more than four inches shorter than when the first dose was exhibited! Other cases of the same nature are related, in which he administered sixty grains of the sulphate at a dose; with the never-failing effect of reducing the spleen at least an inch in all its dimensions within the regular time (twenty minutes) after the exhibition of the remedy (§ 854 bb, 857, 878).

These reports of cases have been extensively circulated, and incorporated into the "experimental philosophy" of the day. Sigmond has a salutary remark upon this subject, which may not be without its

advantages in this place. Thus:

"He who has in early youth sedulously watched the practice of hospital physicians, and has heard from them the mode of management which was formerly pursued; he who has compared what he himself saw at that period, with what he gathers from the most eminent writers, and has then enjoyed opportunities of drawing his conclusions from the bed-side of patients, both in public establishments and at their own houses, will be able to appreciate the difficulties which occur in the application to practice of the rules that are laid down by some individuals with such dogmatic precision; he can also judge of the inutility of those theories which appear based upon plausible foundations, and which are often promulgated by individuals who hastily draw conclusions from few facts, and who commence explanations of their own views, ignorant of what has been thought, said, and practiced by some of the able men who have preceded them; who are again reviving doctrines which time and experience

have already demonstrated to be erroneous. The disregard of physiology and pathology has been one of the great fallacies of the age in which we live. The devotion to morbid anatomy, however praiseworthy is its investigation, has absorbed too much of the consideration of some of our most eminent medical philosophers. They have rather reasoned from the ravages which disease has committed, than from the signs and symptoms, and from the gradual development of the morbid functions of organs. Hence fever has been imagined to be a local disease, and hence the various theories have led not only to unsound, but, in my opinion, to dangerous practice." "The enlargement and induration of the spleen, which attend upon mismanaged intermittent fever, are not uncommonly produced by the neglect of the proper means previous to the use of cinchona, and by its administration in the wrong stage."—Sigmonp's Lectures. London, 1837.

892, kk. In what has now been said of the employment of cinchona with a special reference to chronic enlargements of the spleen (§ 892, k), it is not intended to be implied that the agent is not more or less adapted to such cases; as it is, also, to analogous affections of the liver, &c., which supervene upon intermittent and remittent fevers. But, in all such cases there are other means not less important; such as a well-regulated diet of mild vegetable food, leeching and vesicating the affected region, the local or internal use of iodine, &c. In all such cases, however, the doses of quinia should not exceed one grain; and the practitioner and his patient must yield to the necessities of the case, and be content with advances toward a state of cure that shall correspond, in some degree, with the gradual progress of the disease from its incipient to its aggravated form (§ 150, 548 a, 557 a, 855, 856, 926).

892, l. Pereira has presented a good summary of the effects of quinia in the exclusive practice, as inferred from general experience.

Thus:

"In doses of ten grains, sulphate of quinia has produced on man three classes of effects:

"1. Gastro-enteritic irritation, marked by pain and heat of the gas-

tric region, nausea, griping, and purging.

"2. Excitement of the vascular system, manifested by increased fullness of pulse and augmented respiration. Furred tongue, and

other symptoms of a febrile state, are observed.

"3. Disorder of the cerebro-spinal functions, indicated by headache, giddiness, contracted, and in some cases dilated, pupils, disorder of the external senses, agitation, difficulty of performing various voluntary acts, somnolency, in some cases delirium, in others stupor."—Pereira's Materia Medica.

Here, then, are a great variety of symptoms which denote the pernicious effects of quinia as having followed immediately its exhibition in doses of ten grains, and I have witnessed many of them from five grains only. But, it is these strong demonstrations only which are likely to engage the attention of a large class of practitioners, while the more obscure, but analogous effects of which I have spoken, pass unheeded, or are imputed to other causes.

892, m. Let us, then, look well to the preparatory treatment. Let us scrutinize the varied and exact pathology of the individual cases of intermittent fever; and clear up, at least, any local congestions

that are so apt to stand in the way of the tonic febrifuge. But, let us not neglect the important consideration that these local states are imbued with the special influences of the remote causes of the constitutional affection, and that they are more or less amenable to the Peruvian bark, and would, doubtless, be far more so but for the tonic virtue of the febrifuge (§ 650, 652 c, 662, 670, 814-816, 847 g, 848, 857). Where they are marked by periodical exacerbations they may refuse to yield in their specific nature to all things else than some agent of very peculiar virtues; and here it is that cinchona, or arsenic, manifest their effects as specifics. But it is far from being certain that such agents are indicated because the local conditions of disease do not give way to a direct antiphlogistic treatment. It may be that this treatment has been imperfectly applied, that too little blood, perhaps, may have been abstracted, that leeching or blistering have been improperly neglected, or out of their relative order to general bloodletting and cathartics, or, that some untoward exciting causes, such as errors in food, or fatigue, &c., have been in operation to defeat the right influence of the principal remedies for inflammation These are considerations of great moment, and should duly pass under review in all cases, before we summon to our aid the power in reserve; especially if the local symptoms do not fluctuate like the paroxysms of fever (§ 151, 675, 686, 847 g, 848, 870 aa).

Again, however, cases arise where the local affections put on a distinctly intermitting character. The symptoms of cerebral congestion rise and fall with the febrile paroxysms and the intermissions, or those of pleurisy undergo the same fluctuations. Here, therefore, there is little or no room for doubt, after a full impression has been made by bloodletting, cathartics, &c., upon the general pathological condition. This preparatory treatment adopted, the first moderate dose of quinine will often tell us that it has reached deeply the peculiar modification which had been impressed upon the congested or inflammatory states by the miasmatic cause; while, on the other hand, had the remedies for common inflammation been neglected, and no impression had been thus made upon the universal pathological condition, that grain, or less, of quinia would have exasperated the whole condition of disease (§ 137 d, 150, 151, 650, 672, 673, 801, 814, 857, 870 aa).

892, n. The foregoing peculiarly modified states of congestion and inflammation, in their supposed intensity (§ 892, m), are not, however, common in America; but, it is more common to find that remittent fevers, notwithstanding any remaining congestions with which they may have been complicated, will be ultimately benefited by very small and cautious doses of the cinchona alkaloids (§ 150, 870 aa).

892, o. It should be added that it has occasionally happened within the experience of the best observers, that acute and violent inflammations have occurred independently of intermittent fever, where the inflammation has refused to yield to bloodletting, &c., but has subsequently surrendered speedily to the bark. It can scarcely be doubted, however, that these rare conditions are under the modifying influence of the remote causes of intermittents (§ 150, 151, 813 a, 816).

892, p. Besides the affections which I have considered in the foregoing sections, there are others of an intermitting character to which the cinchonas, and their allies, are especially adapted. These are the well-known intermittent head-aches, intermittent neuralgia, intermit

tent amaurosis, intermittent ophthalmia, &c.; all of which probably depend, for their specific character, upon the vegetable miasmata that lay the foundation of intermittent and remittent fever (§ 150, 650, &c.). Such has been the opinion of those who have lived and written in the midst of such affections. "The same cause," says Tissot, "which produces the intermittent fever, frequently occasions also disorders that return periodically at the same hour, without shivering, without heat, and often without any quickness of the pulse. Such disorders generally observe the intermissions of the quotidian or tertian fevers, but much more seldom those of quartans. I have seen violent vomitings, and retchings to vomit, with inexpressible anxiety, the severest oppressions, the most racking colics, dreadful palpitation and toothaches, pains in the head, and very often unaccountable pain over one eye, the eyelid, eyebrow, and temple, on the same side of the face, with a redness of that eye, and a continual trickling of tears. I have also seen such a prodigious swelling of the affected part, that the eye projected, or stood out, above an inch from the head, covered by the eyelid, which was also extremely inflated or puffed up. All these maladies begin precisely at a certain hour, last about the usual time of a fit, and terminate without any sensible evacuation, return exactly at the same hour the next day, or the next but one."

This reminds us of Hippocrates; and the practitioner in the malarious districts of the United States will not fail to recognize in the graphic portrait the same things in his almost daily walks, as he does

in the "epidemics" of the venerated father of medicine.

The treatment of the foregoing cases is very embarrassing, unless we are prepared by a knowledge of their peculiar pathological character; and, having quoted the experience of Tissot as to their occurrence, I cannot do better than to state the treatment which was pursued by one who is so eminently entitled to our confidence; especial-

ly as that treatment has not been improved.

If the affection was decidedly inflammatory, as in the case of the eye, he abstracted blood. Then he goes on to remark that, "There is but one medicine that can effectually oppose these periodical maladies, which is the bark. Nothing affords relief in the fit, and no other medicine ever suspends or puts it off. But, I have cured some of these disorders with the bark, and especially those affecting the eyes, which happen oftener than the other conditions, after their duration for many weeks, and after the ineffectual use of bleeding, purging, baths, blisters, and a great number of other remedies. If a proper quantity of it be given, the next fit is very mild; the second is prevented, and I never saw a relapse in these cases, as often happens with intermittent fevers." But Tissot had, also, a preliminary treatment.

Tissot wrote before arsenic had come into use as a remedy for intermittent fever, and which has been subsequently employed with

great success for the intermitting headache, &c.

892, q. There is one form of continued fever to which the bark is adapted in its advanced stages, and, what is remarkable, the tincture is often the best, and that, too, where stupor has come on, along with subsultus tendinum, black tongue, sordes, &c. This form of the continued fever is the typhus, and belongs to climates where the intermitting diseases are scarcely known to occur.* In these cases, the

* I have shown in the Med. and Phys. Comm. (vol. 2, pp. 449, 690) that typhus or typhoid fever does not originate in the U. S. south of Lat. 41°. The "fatal typhoid" of our civil war is the congestive remittent fever.—August.—1862.—Note S p. 1124.

bark appears to act both as a tonic and febrifuge. But, it is suited

only to advanced stages of the disease.

892, r. Whenever cinchona, or its alkaloids, prove beneficial under other circumstances than such as have been stated in the foregoing sections they operate in virtue of their tonic property. But, like all other tonics their range of usefulness, in this acceptation, is very limited; being suited only to advanced stages of acute disease, or to some chronic maladies in which digestion is peculiarly impaired, or to others attended by profuse mucous discharges, as in old and excessive bronchial secretion, old diarrheas, &c. Their best effects as tonics are probably manifested in feeble scrofulous habits, when digestion is impaired; and along, perhaps, with iodine. They exert, also, a kindly influence upon the shattered constitutions of old venereal subjects, especially when mercury fails of its usual office, and then, also, iodine should often go with it. They are among the present helps to broken-down debauchees.

Notwithstanding, however, the inconsiderable advantages that arise from cinchona as a tonic, it stands at the head of that group of remedies, as it does in its rank among the special alteratives for intermittent diseases. The contrast in effects separates very widely from each other these coexisting virtues, while the limited advantages of one or its more frequent pernicious effects tell us, forcibly, to beware

of the whole group of tonics.

ARSENIOUS ACID.

892;, a. Arsenious acid, in the treatment of intermittent diseases, has been rapidly passing into the great reservoir of forgotten things; whither it has been driven by the power of novelty, and the superior excellencies of the cinchona alkaloids. But, it remains as ever a sure friend of man whenever his necessities may oblige him to call it from obscurity. It is partly from these considerations, and in part to look at its peculiar attributes as a curative agent, and thus to elicit new rays of light upon organic life and the philosophy of medicine, that I shall venture to disturb the repose of this once busy member of the

mineral kingdom.

But, these objects need not detain us long, as I contemplate a reference mostly to its relations to intermittent diseases; and much of what was said of cinchona is applicable to arsenic. This agent, however, is not complicated by any tonic virtue, as otherwise supposed by many, which divests it of objections that are relative to that characteristic of cinchona.* Yet, it has the attribute of a violent poison, and may, therefore, be liable to disastrous effects from its incautious use. But, with this contingent objection the amount of evil which it has inflicted is insignificant with that which is constantly in progress from the untimely application of the Peruvian bark, or from its excessive administration. In one case the immediate evils are less striking, or creep slowly on; in the other it is death itself who stands before us.

892; b. Arsenious acid appears to be more or less poisonous to all animals. In its therapeutical dose it produces no apparent effect upon man in health; which is only one of the numerous facts that admonish us against all conclusions as to remedial agents from what may be witnessed of their effects upon the healthy system, and to give

our attention to the properties of life as their susceptibilities may be

affected in disease (§ 150, 854, 870 aa, $892\frac{1}{2}$ a).

In respect to the manifestations of arsenic in morbid states of the body, independently of its curative effects, they may be sufficiently learned from a statement by Dr. Fowler, that, "in 320 cases, somewhat more than one third was attended with nausea; nearly one third with an open body; and about one third with griping. Vomiting, purgings, swellings, and loss of appetite were but rare in comparison with the preceding effects, and their less frequent occurrence was generally found in the order in which they are here enumerated. About one fifth of the cases attended with nausea, and one fourth of those attended by an open body, were unconnected with any other effects. Griping did not often occur alone. Purging and loss of appetite seldom or never alone, and vomiting was always accompanied with more or less nausea."

The foregoing observations unfold the nature of the general influences which may be more or less expected from the therapeutical dose of arsenic, and illustrate the fluctuating nature of the organic properties. Such effects, however, may be generally avoided (§ 857).

8921, c. Fowler's Report upon the effects of arsenic appeared in 1786, and subsequent experience has amply established its febrifuge virtue. It appears, indeed, to have succeeded not only occasionally in the hands of most practitioners of experience where the bark and its alkaloids have failed, but even upon an extensive scale in certain epidemical intermittents. It owes, in fact, its early reputation considerably to its success in an intermittent fever which infested Great Britain about the year 1780, and which prevailed for more than two years. But, it was the obstinacy, more than the great prevalence of this epidemic, which renders it memorable; and this the more so from its resistance of the bark, and its submission to arsenic. This was one of the occasions in which the bark fell into considerable disrepute; and we now comprehend the reason of its frequent failure during the epidemic of which I am speaking. Bloodletting was not then the fashion in Great Britain, and this fever was attended by those local congestions and inflammations which either demand the loss of blood, or, at least, render it necessary to any safety in the early administration of bark. But this tonic febrifuge was administered without the requisite advantages of a preliminary treatment, and the local conditions of disease were accordingly exasperated, the fever aggravated and prolonged, and often rendered fatal by the very remedy upon which there was the sole reliance (§ 847 g, 848, 854 bb, 857, 863 d, 870 aa).

However, therefore, the bark may have been thus baffled in its effects as a febrifuge, and inflicted the evils of a tonic, it was no fault of the remedy, but of the practitioners, who neglected the true pathology of the disease, overlooked the local developments, and permitted their prejudices against bloodletting and cathartics to deprive them of the benefits which might have accrued from the Peruvian febrifuge. Being thus baffled in their attempts with an agent of tonic virtues, a few practitioners availed themselves of the reputation which arsenic had obtained in Poland as a febrifuge; and this substance being destitute of the tonic and stimulant virtues of cinchona, it was more compatible with the local condition of disease, and therefore succeeded in the

hands of those few better than the bark. It was apt, however, to occasion vomiting and purging; but these effects were mostly the consequence of a neglect of the appropriate means for subduing the force of the local burdens of disease.

Parallel with the foregoing is an opinion which is thus stated by

Dr. Sigmond.

"The effects of arsenic are much more striking in the intermittent fever occurring during the autumnal months, than during that which is prevalent in the spring; and the more intensely the miasm has acted upon the system, the more decided are its good effects, while cinchona, and the barks of certain trees, produce their characteristic ef-

fects during the spring."—SIGMOND'S Lectures, 1837.

I have quoted this remark for the purpose of carrying out the views which I have expressed as to the failure of the bark in the English epidemics, and as it is its tendency, also, to encourage the use of arsenic in the autumnal intermittents, without any just ground for the conclusion as to its superiority over the bark in the fevers of that sea-The greater success of arsenic as here stated has been observed only in the hands of those who administer the bark indiscreetly, and without properly subduing the local congestions and inflammations which are every where more common and severe in the autumnal than in the vernal intermittents. And, as one of the evidences that the greater success of arsenic, under the circumstances now stated, is due to the absence of the tonic and stimulant virtues of cinchona I may quote the remark from Pereira that, "It is not necessary to intermit the use of arsenic during the febrile paroxysm. In agues, accompanied with inflammatory conditions, where cinchona and quinia disagree, arsenic may, according to Dr. Brown, be sometimes admin istered with the best effects." It has, he says, no tonic virtue.

Immediately after the events of the British epidemic of which I had been speaking, Dr. Fowler appeared with his "arsenical solution," or the liquor potassæ arsenitis; which has been supposed by many to surpass the arsenious acid in its remedial virtues. This preparation became the means of establishing, rapidly, the character of the new

agent all over Europe.

 $892\frac{1}{4}$, d. The question arises, next, as to what conditions of intermittent fever arsenic is applicable in preference to cinchona. We have seen that the bark and its alkaloids are capable of surmounting the disease with great certainty and rapidity under its ordinary conditions when properly administered; and this qualification supposes that other remedies, such as bloodletting, and especially cathartics and antimonials, shall be brought into operation whenever demanded by the general or local symptoms. The disease, being thus treated according to its variable pathological conditions, and the Peruvian febrifuge withheld till its application is compatible with the pathological states as meliorated by the direct antiphlogistics, we may, un doubtedly, in almost all cases which are seen in their early stages, succeed completely with the alkaloids, and thus avoid a remedy, which, like arsenic, is liable to the objections of being fatal in the dose of a single grain, or of inducing violent symptoms, or of laying the foundation of other serious and even fatal affections, in its usual therapeutical doses, if administered in inauspicious conditions of the system, or when continued, under favorable circumstances, beyond a certain

QQ

period. These considerations leave no doubt, therefore, that the alkaloids should be first employed in every case of intermittents, whether they be of fever, or of those other local diseases having periodical paroxysms, as considered in sections relative to the bark. Such, indeed, were the conclusions of the soundest medical experience before the introduction of the cinchona alkaloids; and, while balancing the merits of these remedies we cannot too well consider the safety of one when employed with a proper reference to pathological conditions, and the dangers of the other, under all conditions, that are liable to accrue from over-doses. But this objection applies only to the careless, and may be predicated of many other remedies in common use. We must take the world, however, as it is, and not as it should be; and when, therefore, as in the case before us, a choice exists, let us banish the evil as far as the choice extends. It should still, however, be recollected that, in the case of the bark, a morbific virtue may be in operation in the therapeutical doses of that agent, while the same special virtue does not appertain to arsenic (§ 150, 847 g, 848, 859, 863 d).

It appears, therefore, that arsenic will be wanted mostly in neglected or badly-treated cases of intermittent fever; and the former will be more likely to yield to other means than the latter. In the neglected cases, disease can, at most, have been aggravated only by errors on the part of the patient, while art, with its powerful morbific agents, may lay the foundation of very intractable local maladies that shall impart great obstinacy to the constitutional disease, as unintermitting exciting causes (§ 659, b). Cases undoubtedly arise, also, at certain seasons of the year, such as the autumnal (§ $892\frac{1}{4}$ c), to which arsenic is better adapted than quinine, or where the latter may fail on account of its tonic virtue. Again, other cases sometimes present themselves at all seasons where the vegetable remedy fails under the most judicious treatment. This may be owing to very peculiar modifications of the pathological states, or to unusual affections of certain parts, or to some idiosyncrasy. In short, arsenic is the next remedy, appertaining to the group before us, which should be tried after the failure of cinchona. But, it by no means follows that agents from other groups may not be equally or more appropriate. It happens, frequently, in prolonged or badly-treated cases of intermittent fever where the liver or spleen becomes the seat of enlargements and indurations, that iodine may be employed very successfully in conjunction with quinine. The accession of these two agents to the Materia Medica has contributed, largely, in this as in other respects, to the facili

It has placed, indeed, the foregoing affections greatly under the control of either; and, what is very important, where the bark was inadmissible during the coexistence of fever with the chronic derangements, quinine is often adapted to both conditions; so only, the treatment be properly conducted in its other details. Iodine, however, is only appropriate after an ascendency is obtained by other remedies over the febrile state, and where the force of the local affections has so yielded that they inflict no exciting reflex nervous influences upon the organs of circulation. Otherwise, that intensity should be first moderated by leeching, blistering, low diet, &c. With this qualification, and in the absence of fever, iodine has contributed not a little toward the exclusion of arsenic from the treatment of agues.

In some of the conditions of which I have just spoken, arsenic is advantageously associated with quinia, or administered in the associated form of a salt.

892½, c. We finally come to the conclusion that arsenic ranks next to cinchona in the certainty with which it overcomes intermittent fever. But, it is less certain, and less rapid in effect; and the objection which applies to it as an energetic poison in over-doses should hold it in reserve, to be employed only where cinchona, or quinine, properly administered, may fail. Such as may study disease in its philosophical aspects, taking a comprehensive survey of its varied pathological conditions, firmly resisting the prejudices which timidity or ignorance have heaped upon bloodletting, and who prescribe for the absolute conditions rather than for the name of a disease, will rarely find it necessary to have recourse to arsenic in the ordinary forms of intermittent fever.

892½, f. It is not improbable, however, that this agent may be found more useful in the distinctly intermitting inflammations which accompany marsh fever. It is always difficult to adapt even a cinchona alkaloid to these inflammatory states, while it never fails to exasperate the inflammation if administered before a strong impression has been made by bloodletting and other antiphlogistics.

892½, g. Intermitting headache is a more common form of periodical disease than inflammation, in which arsenic proves often useful, and frequently where cinchona has failed. And so, also, of periodic

tic douloureux.

8921, h. Besides the intermitting affections, there are others to which arsenic is well adapted, and which strikingly illustrate the profoundly alterative and comprehensive remedial virtues of this agent. These remaining conditions of disease are so evidently different from the intermitting, that I have reproduced the arsenical preparations in two other groups of remedies, in my Materia Medica. It is important, in the first place, to regard each remedial agent of two or more virtues as a whole, and to consider its operation under its compound aspect. But, in this state of complexity they cannot be brought into that practical use which is promoted by the method which I have projected of considering the various properties of remedies in an individual sense, and according to the prominent conditions of disease to which they are suited, and by associating under the several denominations of disease the various remedies adapted to them, and in the relative order of their therapeutical value, and, therefore, presenting under each denomination groups of remedies having certain remedial virtues analogous to each other, however they differ in other properties, or however different may be the special influences by which the various agents under any given denomination of disease establish those changes which give to Nature the recuperative start. In this manner a single compound remedy comes to be distributed into what is equivalent to several agents; each remedial adaptation to possess an individuality which distinguishes it from other remedial virtues that qualify the agent as a remedy for other morbid conditions. In this way, I say, we avoid a confusion which has prevailed so extensively from considering a remedy of compound virtues in its general aspect alone. We are led to an attentive examination of its several virtues, of their critical relations to different pathological conditions and thus to acquire a more distinct apprehension of the properties of life, of the modus operandi of remedial agents, and of the laws which govern the organic being under all his conditions of health and disease.

8921, i. The diseases which fall, more or less, under the power of arsenic, and which illustrate the extent of its remedial virtues beyond those which have been hitherto considered, consist of certain chronic eruptive affections of the skin, cancer, noli-me-tangere, chronic rheumatism, diseases of the bones, chorea, elephantiasis, &c. In some of these conditions, especially in cancer, it is applied externally as well as internally. Iodine has been also advantageously associated with arsenic in the treatment of some of these affections.

 $892\frac{1}{4}$, k. The variety of diseases to which arsenic is adapted, and its inertness upon the healthy body in its therapeutical doses, illustrate my doctrines of operation through alterative reflex nervous actions, and of the increased susceptibility of morbid states (§ 143 c, 222-233 $\frac{4}{5}$, 500 m,

892 b, 892½ v, 900, 902, 1059).—Note L p. 1120.

IODINE.

 $892\frac{1}{2}$, a. Considering the extensive and powerful nature of the alterative action of iodine, it is remarkable that in its small therapeutical doses it produces no well-marked effects upon the function of any organ in its healthy state. In this respect, therefore, it goes with arsenic, and the rest, in illustrating the nature of life, and in enforcing a limitation of inquiries into the therapeutical capabilities of remedial agents to morbid states of the body (§ 137 d, 150, 854 bb, 870 aa, 892½ b). When its use is long continued, emaciation is said to have sometimes followed, and now and then a low state of gastro-enteritis has been supposed to have supervened when iodine has been employed in large doses. This, however, is considered a rare effect, and to depend upon the incautious use of the medicine. It has doubtless happened in morbidly irritable states of the alimentary canal (§ 137) d, 150). Lugol, who had great experience with iodine, says, that so far from even occasioning a wasting of the body it promotes growth, and increases the size of organs, in their healthy state. The nervous system is said, also, to have been occasionally disturbed, in natural states of the body, by therapeutical doses of iodine; attended by headache, giddiness, &c. But here, too, there had probably been an antecedent derangement of the alimentary canal, &c. It has been also laid to iodine, that it has occasioned a state of the system which merits a name significant of one of its morbific tendencies; and hence that of iodism has been associated with the remedy. This condition is marked by vomiting, purging, cramps, emaciation, fever, &c. But, I am apt to think that the fault, in these cases, is chargeable to maladministration. Others have affirmed that iodine has occasioned salivation; but this, also, is denied by others. In any event, such a result is extremely rare. Twelve grains, on an average, have been given daily for eighty days, making 960 grains, without any manifest effect. In excessive doses, however, iodine is capable of acting as an irritant poison; or, should disease be present, the whole aspect of the subject is changed. I have never witnessed any of these alleged effects.

A remedy, therefore, so exempt from all untoward action upon the healthy body, and, withal, as inoffensive when skilfully used in morbid states, yet capable of a vast range of the most important remedial effects, must be regarded as an accession to the Materia Medica

of great value.

8921, b. I have been thus led to consider the failures of iodine upon the body in a state of health, in its ordinary doses, for the purpose of contrasting them with some of the remarkable therapeutical influences of which iodine is capable, and to show how the vital states are changed in their relation to remedial agents by morbid states. This, however, may be equally instituted with many other very powerful remedies, even those which are liable to act upon morbid states, in their therapeutical doses, with the intensity of energetic poisons, or strike at other alarming maladies, yet manifest no sensible effects upon the healthy organism (§ 137 d, 150, 870 aa, 892\frac{1}{4} b, k, Note L p. 1120).

8921, c. Perhaps the most remarkable demonstration of which iodine is capable is in those latent forms of disease where nothing is present to denote the morbid state but some gradual change of organization. This is seen especially in bronchocele, for which affection it surpasses, greatly, any other remedy. And here it may be said, as indicative, in every aspect of the subject, of the vital philosophy of the operation of iodine, that it is often as efficient in most of the local forms of disease for which it is employed whether it be administered internally, or applied externally. It is also an important fact, of the same import, that the external application must be made over the region of the affected part, when disease is seated internally; in which respect its mode of action through a reflex nervous process borrows light from the modus operandi of counter-irritants. Its control over the ordinary form of bronchocele is thoroughly established, and where it has failed I have no doubt it has been generally owing to some defect

in the treatment (§ 893 a, c, e, m, $905\frac{3}{4}$, 1059, 1088 b).

I say, the common form of bronchocele; for there are some conditions of the thyroid gland which nothing will reach; which is one of the endless exemplifications of the importance of addressing our remedies to the exact pathological condition. Now the true bronchocele is constituted by a low indolent action of an inflammatory nature, that which results in hypertrophy; better known at present as a "lesion of nutrition." To these lesions iodine is adapted; and, although it seek out the obstinate forms of disorganization, there are some morbid changes of the thyroid gland which have been mistaken for bronchocele where this agent has disappointed expectation, and has suffered the blame of another's fault. Among these intractable conditions are formations in the gland of other substances than deposits of lymph, such as stony and other concretions. Or, again, the organ takes on a scirrous condition. Or, at other times, it enlarges suddenly, and shows high vascular action, which ends in an effusion of serum; the gland becoming enlarged in consequence. But this condition is not apt to remain long; and, although it subside spontaneously, it is not amenable to iodine. The remedies consist of leeches, vesicants, &c.; and, if such treatment be applied to the indurated states of bronchocele, preliminary to the use of iodine, this remedy will not often fail of accomplishing the residue of the cure. It is also indispensable to subdue, in the first place, any attendant excitement of the general circulation, or functional derangement of the chylopoetic viscera. These, indeed, are important objects of attention, whatever be tne nature of the disease for which iodine may be prescribed. The

external use of iodine, in the treatment of goître, is not less efficient than the internal; so that both methods may be associated. Or, where objections apply to the more constitutional mode, the local application is often admissible. But iodine will not, like the mercurials, extend its influence over the system through the medium of the skin. Its effect is then by local reflex nervous actions (§ 497, 893 e, 1059, 1088 b).

 $892\frac{1}{2}$, d. Soon after the discovery of iodine Dr. Coindet applied it successfully to the cure of scrofula. His observations were soon followed up by others; so that the claims of the remedy became early established in respect to this most intractable disease. Numerous cases and memoirs were published, all tending to advance inquiry into the new and extraordinary agent; extraordinary as well in its relations to the inorganic as the organic world. It was early and successfully tried upon an extensive scale by Dr. Manson in various conditions of scrofula, scrofulous ophthalmia, &c.; employed both internally and externally. Then followed Lugol, attached to the hospital of St. Louis, who published three memoirs confirming the favorable report of his predecessors. This narrative seems to be due to the early founders of a remedy which has already bestowed incalculable blessings upon man; approaching even cinchona, since we had in arsenic, and numerous other means, pretty good substitutes for that. And now, when we pause for a moment over the countless numbers who have been already rescued from the grave by iodine alone, and when we attempt to think of the labyrinth of medical philosophy through which the enlightened physician directs, with so much relief to the whole race of man, the most potent, as well as the milder agents, of the Materia Medica,—ay, the remedium principale itself, what shall be said of that credulity of the public which reposes its confidence in the charlatan, or yields the Pæan triumph to an Apollo in surgery?

Lugol's authority is valuable. His experience has scarcely been improved. He employed the remedy internally and externally, and treated the various conditions to which scrofula is liable, from the simple glandular swelling, ulceration, abscess, &c., to its destructive effects upon the cartilages and bones. An exception, however, must, and probably always will, be made in respect to tuberculous phthisis. He prefers a solution of iodine with the iodide of potassium, in water. This he administered either in the form of drops, or largely diluted with water under the denomination of ioduretted mineral water. has become, indeed, a standing formula; but to which there is the same objection as applies to all other analogous prescriptions. They all require variations in the relative proportions of their constituent parts, and lead to a neglect of the varying pathological states of a common form of disease (§ 150, 672, 673, 857, &c.). It is doubtful, however, whether the union of the iodide of potassium often increases the efficacy of the simple iodine; although the salt, being less energetic, is often better adapted to irritable states of the alimentary canal, or where the circulatory organs are liable to excitement. It is readily seen, therefore, that for this reason the iodide of potassium may be often united in variable proportions to the more active and

irritating form of the remedy.

892½, e. It should be considered, however, in reviewing the favorable reports which have been made of a new remedy, that here, as in most other cases, other observers have been less successful with iodine;

though a general admission obtains that it is more useful in scrofulous affections, with the exception of phthisis, than any other agent. therefore, is sufficient to place it upon very high ground as it respects the most Protæan disease. There is much reason to think, however, that those who have been least successful have often failed from not having bestowed the same attention upon those general means of improving health, such as diet, warm clothing, exercise, &c., which are. of themselves, not unfrequently curative of scrofulous affections; as they are of syphilitic. When remedies are employed in any given disease for the cure of which they have acquired the reputation of specifics, we are often apt to rely too exclusively upon the supposed specific, and the remedy, in consequence, frequently fails when it would have succeeded under a proper regard for the subordinate Failure in this respect may turn the "specific" into a formidable foe, especially in active forms of disease (§ 137 d, 150, &c.).

Again, since the early day, recent to be sure, of the wonder-working power of iodine, the reputed pathology of scrofula has undergone a revolution; and where abstraction of blood, general or local, a nonstimulating diet, &c., were often considered necessary, especially in the primary stages of phthisis pulmonalis, a tonic and stimulant treatment has been erected upon the new doctrine (§ 4, 51/4. Also, Med. and Phys. Comm., vol. ii., p. 608-634, 743-746, 780-782). From my own observation, I can entertain no doubt that iodine is yet destined to yield a subordinate aid in the treatment of tuberculous phthisis; while it will rarely fail to aggravate the disease if employed before inflammation is brought under the discipline of the lancet, low diet. &c., or where the alimentary canal, or the system at large, is in an ir-

ritable state.—Note F p. 1114, Mm p. 1141.

892½, f. Thirdly. The power of iodine, and of its combinations, reaches yet farther, and more remarkably, perhaps, than as respects its control over bronchocele. It has often accomplished the removal of certain chronic affections which appeared to have been excluded from the reach of every other medical agent. This has been especially true of many cases of those affections which have run on to induration. Here it is that iodine illustrates its remarkable virtues as an alterative, in breaking up the most obstinate conditions of disease, changing entirely the long-established morbid action of those capillaries from which the deposition of a peculiarly modified condition of lymph arises, and which forms some of the worst enlargements and indurations short of carcinoma (§ 733 f, 738, 740 a, b); while, also, its sanative effect must extend to the absorbent system of the part, increasng its energy, and thus reducing the volume of the organ and restor-Mercury, it is true, will accomplish this in ing it to its natural state. some instances, but is comparatively inoperative, and they are beyond the reach of quinine.

So also in those chronic enlargements and indurations of the liver and spleen which form the sequelæ of intermittent and remittent fevers the Peruvian alterative finds a competitor in iodine, though they will now harmonize together (§ 892, kk). Mercury, too, in some of its forms, is also more or less applicable to these conditions. But, to iodine we look with greater confidence in the intractable shapes; and here we may not calculate much upon the cinchona alkaloids. Nevertheless, even here mercury may be often advantageously associated with iodine; and this is particularly true of bad forms of hepatic induration. Iodine, however, is more apt to take in its therapeutical scope those enlargements of the spleen which are known as ague cakes. They have often yielded to its influence in this and ir other countries; and sometimes, indeed, where the splenic induration has been independent of fever, and where quinia is powerless (§ 662 a, 813 b, 814, 816 b, 892 kk). Leeching often promotes their effect.

The uterus, in its former intractable indurations and enlargements, has frequently yielded of late to the alterative action of iodine. Even when of a bony hardness, and filling nearly the cavity of the pelvis, this condition of the uterus has given way to iodine in the space of six weeks, the volume of the organ reduced to the natural size, and the catamenia restored. Here the dependence was upon iodine alone; and justly so, since there was no local or constitutional inflammatory symptom to require the co-operation of a depletory treatment. But, in other examples, where more or less active inflammation has attended the uterine enlargements, local and general bloodletting, rest, low diet, &c., have been brought advantageously to the successful use of iodine (§ 855, 856). It is astonishing, too, with what rapidity these conditions of the uterus have given way; yielding entirely, in the most successful cases, within periods varying from six weeks to four months.

These uterine cases, like the ophthalmic, illustrate the safety and advantage of applying iodine directly to the affected part, wherever accessible; it being rubbed, in the form of an ointment, in the case of the uterus, upon the neck of that organ. This practice has succeeded especially where the neck of the uterus has been the special seat of induration, and of those hard tumors which are liable to run into

ulceration.

Iodine has even made salutary impressions upon ovarian tumors; and here, also, it is mainly useful in the indurated enlargements of the

ovaries, and probably little, if at all, in ovarian dropsy.

Leaving the uterine system for its associate mammary gland, we have many accounts of its partial success, at least, in those scirrous affections which put on some of the aspects of cancer, but without its malignancy; relieving the distress, and holding the disease in check; while even cancer itself, and in its ulcerated state, is said to have derived mitigation from the external use of iodine.

Few affections are more sad than enlargements and indurations of the prostate gland; and here, too, the sufferer has sometimes obtained relief from this remarkable agent, both from its internal and external use.

The parotid glands swell up and remain permanently enlarged and indurated after scarlatina, and from other transient causes; and the lymphatic glands become involved in the same way from sympathy with diseased states of the stomach, or from other causes not connected with the scrofulous diathesis. In all these cases, iodine is the most efficient agent; at least, in a general sense. But these are cases, also, for leeching; which not only greatly helps the restorative change, but imparts, also, greater efficacy to the iodine. Indeed, it is not unusual that repeated applications of leeches to these glandular tumors, although of an extremely indolent nature, will alone overthrow their morbid states, and disperse the whole affection. It is a common mode of treatment in my practice, and has often revealed an alterative influence of the remedy of which cupping is incapable (§ 893 a, c, q, 926).

892½, g. Iodine has been employed internally and externally, with various degrees of advantage, in chronic affections of the skin, such as lepra, i hiosis, psoriasis, &c., and it has been applied in the same way to arrest the progress of phagedenic and other destructive ulcers, which often put on favorable changes under the local as well as constitutional effects of this agent; which is also equally true of bromine.

892½, h. Nor has secondary syphilis refused to yield to the power of iodine; and this, too, in cases where mercury has either failed, or has aggravated the affection. But, these cases are not common, and we should not be led away from the better remedy by rare examples of greater success from an agent which will commonly fail. Where iodine has succeeded in cases of this nature, without the cooperation of mercury, the syphilitic affection may have been under the influence of the scrofulous diathesis (§ 659, 662 a). Besides the internal proof concerned in these cases, the foregoing conclusion is strengthened by the emaciation, ulcerations of the skin and throat, and the inflammation of the bones and periosteum, which often attend cases where iodine has exerted an independent sway.

But iodine has succeeded most happily in syphilitic cases when combined with mercury; especially where syphilis has affected scrofulous subjects. But simple iodine, true to its great prerogative of overthrowing deep-seated mischief of chronic glandular inflammations, has been successfully applied to old venereal affections of the testicles,

and to indolent buboes.

 $892\frac{1}{2}$, i. Gonorrhæa and leucorrhæa, in their indolent states, have been successfully treated by iodine; especially so in scrofulous habits,

when the relief it yields is more uniform than in other cases.

892½, k. I stated just now, that iodine has been more successful in real ovarian tumors than in simple ovarian dropsy; but other dropsical affections have not escaped the far-reaching virtues of this new agent; though I have not much to say in commendation of its efficacy on this score. As in many other affections, it is evident that iodine delights in the worst forms of dropsy, and is little disposed to grapple with those simple conditions which depend upon mere inflammation of the serous or cellular tissues. It makes its attack, rather, upon those dropsies which nothing else will reach; such as are symptomatic of organic affections of the liver, or kidneys, or spleen, or heart, &c., and where a low inflammation is instituted, sympathetically, in the serous tissue of the abdomen or thorax, as the immediate proximate cause, and kept up by the organic disease. And now we understand how it is that iodine will sometimes reach these most formidable dropsies, since it is the peculiar province of this agent to break up old organic lesions; and, in exerting this astonishing office in regard to the liver, &c., the cause which maintains the serous inflammation is removed, and the dropsical affection disappears as a consequence. Hence, again and again, the importance of looking well not only to the nature of the pathological cause, but to all the complications with which it may be attended, and their sympathetic relations to each other (§ 905).

892½, l. Iodine has been successfully employed as an emmenagogue by most of the physicians who have illustrated its uses. My own observation leads me to believe that it is mostly useful in restoring menstruation in subjects of a scrofulous diathesis; and here it will be sal-

utary, if not contra-indicated by irritable states of the stomach and intestines. But, even in such cases the iodide of starch, or the milder sponge, may be admissible; and this remark, it will be readily seen, is more or less applicable to other affections attended by morbid irrita-

bility of the gastro-intestinal mucous tissue.

The same agent is also entitled to much consideration as an indirect emmenagogue in all cases where suspended menstruation is complicated with chronic enlargements or indurations of any of the great internal viscera. In these instances the uterine affection is only symptomatic of graver disease, as, indeed, it may be said, in a majority of other cases, to depend upon a primary though only simple derangement of some other part, especially of the alimentary canal (§ 689 l, 905), the uterus being disturbed by reflected nervous actions.

892½, m. Chronic rheumatism has proved itself amenable, in some cases, to iodine. We shall find, however, much better remedies for rheumatism, in all its aspects. But, it is not remarkable that a power so sovereign in many other intractable maladies should sometimes succeed in whatever less difficult and somewhat analogous instances it may be brought to bear. It must be considered, also, that the scrofulous diathesis is common, and that here iodine is at home.

892½, n. In the form of iodine vapor the novelty is even held up as a remedy for pulmonary consumption by Sir C. Scudamore, Sir James Murray, and others. But, it is scarcely probable that this condition can be affected in any other way than through the constitutional method, and it may be expected that the vapor will share the fate of

boiling tar, and the steam of the horse-stable.

 $892\frac{1}{2}$, o. Gout has yielded to this potent but quiet remedy. The swellings of the joints have given way not only in chronic, but in some acute forms of the disease. Those practitioners who have employed it in the latter case are probably of them who cure the same disease with bark and wine, and it has been overrated in the former. With the same experimental views iodine has been administered in diabetes mellitus; but, whether it may be useful or detrimental in this disease will depend, clearly, upon the circumstances of each individual case; especially upon the state of the digestive organs, which take an important part in the pathology of diabetes (§ 1007 c).

\$92\frac{1}{2}, p. Iodine is employed by the surgeon for various local purposes, among which many forms of ill-conditioned ulcers are the most common. Here it often manifests its sanative influence, but more so when the cases justify its internal use. It were well, too, if these cases were oftener treated according to the precepts of medical phi

losophy and the experience of sound physicians.

 $892\frac{1}{2}$, q. The ioduretted bath has been overrated, and the proof is against the supposed absorption by the skin (§ $892\frac{1}{2}$ c, 1088 b, c).

The details as to dose, &c., must be sought by the young inquirer in the appropriate books. There, too, he will find some useful combinations of this with other substances, which have been brought together by the chemist, who is always laying the profession under these high obligations. We shall not often want, however, more than the simple substance, the iodide of potassium, the iodide of mercury, and the iodide of starch. It is not improbable, also, that we may sometimes find in bromine, or some of its combinations, useful substitutes for iodine.

892½, r. I have spoken of the iodide of starch as suitable in many cases where the intestinal canal, or the system at large, is too irritable for the more active forms of iodine. But, I am apt to think that, in such cases, we may also fall back advantageously upon the vegetable æthiops, or upon the burnt sponge. They have done us service in

former times, and may do it again.

It is certainly a curious fact, in the history of the Materia Medica, that the fucus vesiculosus and the sponge, one an unseemly weed of the ocean, and the other an anomalous organic being from the bottom of the Mediterranean, should have been applied to the relief of bronchocele and scrofula, and have led to the important supplement which the Materia Medica has enjoyed in the iodides and bromides. Nor is it less curious that a remedy for the same affections had been detected in the liver of the cod.

Although the day of these mysterious agents has passed away,—passed in their uses and their mystery,—it may be that exigencies may now and then commend to our notice their quiet influences; when we may depend upon it we shall find organic nature as undeviating in these low conditions of life as in all other objects within its comprehensive range. We shall always find iodine and bromine among these humble tenants of the deep; and, in doses of one drachm to four of the calcined preparations, we may depend upon results, if not as certain and speedy as those of iodine or bromine, at least such as will evince an efficient remedial power (§ 290, 350, nos. 25, 26,

 $26\frac{1}{2}$, 28).

892½, s. It sometimes happens when iodine, or its compounds, irritate the intestinal canal, or the system at large, they may be rendered compatible by small quantities of morphia, or the extract of hyoscya mus, or of lettuce, &c. This interposition of narcotics, however, to promote the tolerance of iodine, demands great care; and the narcotic must not be detrimental if the iodine were not employed. But, it commonly happens, when iodine produces its salutary effects, that it improves the appetite, if it have been deficient; or, at least, does not impair it. In a general sense, also, if the subject have been thin he gains in flesh under its influence. These affirmations can be made of no other remedy, excepting bromine, of equal curative power. It is often, indeed, upon the digestive organs that the first salutary effects of iodine are manifested; as seen not only in the improvement of appetite and digestion, but in the more abundant elaboration of bile, and in a healthier aspect of the fecal discharges. Simultaneously, also, the bowels act more freely; and, when purging takes place during the use of iodine, it is probably often more from the redundant flow of bile which it has promoted than from the direct action of the remedy upon the intestinal canal.

892½, t. Here, then, through these effects upon the organs of digestion, we arrive at an interpretation of those salutary changes which are exerted upon parts remotely situated. It is either a direct sympathetic result, or the sympathetic consequence of the removal of disease from the abdominal viscera, by which the remote affections had been maintained, as expounded in § 226, 503, 524 c, 893 a, c, 905.

892; u. In a general sense, it has been found that a non-stimulant diet promotes the salutary effects of iodine. This agent is, in itself, a stimulant to the circulation in most of the morbid states to which it is

applicable; and, while it heals by other virtues, its stimulant properties disqualify it for all active conditions of inflammation (§ 137 d, 143 c, 150, 151). It is therefore an object in the lower forms of inflammation which come within the range of iodine to avoid increasing the susceptibility to its stimulant virtues by stimulating food (§ 143 c, 556 c, 872 a). In such conditions, indeed, abstemiousness, in respect to food, is in itself directly curative (§ 150, 856, 863, 1007 b-d, 1008).

But, there are some conditions to which iodine is peculiarly suited, particularly bronchocele, when the general health is often sound, and when the ordinary diet may be pursued (§ 143 c, 150, 151, $892\frac{1}{2}$ a). In most other affections to which iodine is adapted the general health is apt to be unsound, and the local affections of a distinctly inflamma-

tory nature.

 $\$92\frac{1}{2}$, v. When speaking of cinchona and other special remedies for specific forms of disease (\$~892~b), I endeavored to demonstrate not only their therapeutical effects through alterative reflex actions of the nervous system, but, by the variety of means leading to a common result, the absurdity of the humoral and chemical hypotheses, and I would now reproduce that section in connection with iodine; nor would it be less appropriate to the article upon arsenious acid ($\$~892\frac{1}{4}$). The great variety of special forms of disease which iodine and arsenic will remove contributes to the demonstration ($\$~892\frac{1}{4}$; $892\frac{4}{5}$; 9,900,902,951~c).

ERGOT.

 $892\frac{2}{3}$, a. The origin and special character of ergot have been only recently well determined. Many have supposed it to be a morbid conversion of the seed, produced by some insect. Others regard it as a parasitical fungus; and it is incorporated by them as a true plant in the genus selerotium. It has been shown, however, by Tessier, and others, that a part only of the grain sometimes becomes ergotized; which proves sufficiently that it is not a fungus. The stigma, too, often remains at the top, and the ergot, like the rye, is intimately connected with the receptacle. Other observations, more recently made, prove conclusively that the microscope has been at fault, even in this very visible and hard substance, in its report of parasitical fungi as constituting the ergotized rye (§ 83 b, 131). The ergot is now sufficiently shown to be a morbid degeneration of the rye.

8922, b. Ergot was introduced into regular practice, as a powerful agent for exciting uterine contractions during the process of labor, by the venerable John Stearns, M.D., of the city of New York, in a letter to Dr. Ackerly, in 1808; though it had been a popular means of expediting labor a century and a half ago, in Germany, Italy, and

France.

This letter of Dr. Steams has not often met the public eye, nor has that reward attended the service which it was the delight of darker ages to bestow upon the great benefactors of man. The letter, too, is interesting from the brevity with which it announces a most important discovery (new at least to the profession), for the perfect accuracy with which the effects are described, and for the precautions which Dr. Steams had the sagacity to suggest as to the circumstances under which this agent should be administered, but which have been most strangely violated by others.

The brief statement, which has now grown into volumes, of the wonderful properties of ergot, and of the only known substance which is capable of exciting uterine contractions, contrasts in its brevity and modesty not less remarkably with the never-ending and inflated accounts which are often coming to us of worthless specifics, and more worthless speculations, than does the decisive power of ergot form an imposing contrast with the whole host of those pretended remedies which have fallen into oblivion, one after another, when their inefficiency has been proved by an adequate sacrifice of human life.

But let us once more call into light the original announcement.

Thus the letter:

"In compliance with your request, I herewith transmit to you a sample of the *pulvis parturiens*, which I have been in the habit of using for several years with the most complete success. It expedites lingering parturition, and saves to the accoucheur a considerable portion of time, without producing any bad effect on the patient.

"The cases in which I have generally found this powder to be useful, are when the pains are lingering, or have wholly subsided, or are in any way incompetent to exclude the fœtus. Previous to its exhibition, it is of the utmost consequence to ascertain the presentation, and whether any preternatural obstruction prevent the delivery; as the violent and almost incessant action which it induces in the uterus precludes the possibility of turning. The pains induced by it are peculiarly forcing, though not accompanied by that distress and agony of which the patients frequently complain when the action is much less. My method of administering it is either in decoction or powder. Boil half a drachm of the powder in half a pint of water; and give one third every twenty minutes till the pains commence. In powder I give from five to ten grains. Some patients require larger doses, though I have generally found these sufficient.

"If the dose be larger, it will generally produce nausea and vomiting. In most cases you will be surprised with the suddenness of its operation. It is, therefore, necessary to be completely ready before you begin the medicine, as the urgency of the pains will allow you but a short time afterward. Other physicians who have administered

it concur with me in the success of its operation.

"The modus operandi I feel incompetent to explain. At the same time that it augments the action of the uterus, it appears to relax the

rigidity of the contracted muscular fibres.

"It is a vegetable, and appears to be a spurious growth of rye. On examining a granary where rye is stored, you will be able to procure a sufficient quantity among the grain. Rye which grows in low, wet, ground yields it in greatest abundance. I have no objection to your giving this any publicity you may think proper."—John Stearns, in

New York Medical Repository, vol. xi., p. 308, 1808.

That is the whole; correct in every aspect, and without a practical improvement from that day to the present; unless it be an extension of some of the minor points which are embraced in the comprehensive statement of the discoverer. It may, therefore, stand as an admirable concentration of all the leading details relative to this great accession to the universal cause of humanity and medical science. It is the best general guide for the practitioner that can be devised, and had it been duly posted in medical journals and obstetrical works, in-

stead of some of its violations which have appeared from time to time, it will be conceded, I cannot doubt, that I am not astray from the objects of the present work in bestowing an ample notice of the origin of an important remedy which stands alone in the natural world.

No sooner was this discovery announced than its value was proclaimed in different quarters, not only by a confirmation of the imputed virtues of ergot, but by an opposition to its use on account of those very attributes of the remedy. It was said to be dangerously violent in its uterine influences. And so it is, like all things else in their various relations to disease unless employed with a proper reference to "precaution" (§ 137 d, 143 c, 150, 151).

With others there was not a ready disposition to concede the merit of originality, and records were hunted up for the purpose of showing that ergot had been long before in the hands of the common people, about in the same way as had been the cow-pox before Jenner confirmed its protective power. But, whether the former was of any greater use than motherwort the profession had not troubled themselves to

inquire.

Frightful accounts were also quoted of wide-spread and fatal epidemics, which had been commonly charged upon rye, of which ergot was supposed to be the insidious cause (§ $892\frac{3}{4}$, l). A more feeble conjecture was never assigned for epidemics; unless the hypothesis be excepted, that damaged rice was the cause of the malignant cholera in Asia and Europe, because the patients had "rice-water evacuations;" and, also, that the milk of cows in some of our Western States is the cause of a malignant form of miasmatic fever (Med. and Physiolog. Comm., vol. i., p. 537–539).

Other writers entered the field against the new agent in other shapes; some of them denouncing the remedy as invariably fatal to mother and child, while others affirmed that it was as inert as rye itself.

But time puts all things right, though it may come too late for him who should reap the reward. Harvey lost all his practice because of the envy which was excited by his discovery of the circulation of the blood; and nothing but demonstration upon demonstration to the eyes of the multitude rescued Jenner from the execration which he received because he had been so unfortunate as to render a great service to his cotemporaries. Newton, too, was so annoyed by opposition that he regretted his pursuits, and has left, in consequence, his stamp upon the very front of Philosophy, that she is "a capricious maid." But there is this consolation, as Bacon has it—"The sweetest canticle is, 'Nunc dimittis,' when a man hath obtained worthy ends and expectations. Death has this also, that it openeth the gate to good fame and extinguisheth envy: 'Extinctus amabitur idem.'"

It was not so in the early ages of our art; and had Harvey, or Jenner, or Stearns, have lived at that remote period, temples would have overspread the land for the perpetuation of their names, and as grateful memorials for their services to the universal family of man-

kind.

8923, c. Ergot is poisonous to flies, leeches, and some other small animals. In very large quantities it is said to be destructive to dogs, cats, pigs, sheep, rabbits, fowls, &c. But this effect has been evidently overrated, since it appears that some ounces were necessary to affect rabbits and pigeons. Sheep are put down by Pereira, in his

Materia Medica, among the animals that are liable to be poisoned by ergot. But a little farther on he says that, "In 1811, twenty sheep ate together nine pounds of it daily for four weeks, without any ill effects. In another instance, twenty sheep consumed thirteen pounds and a half daily, for two months, without injury." And then as to other animals: "Thirty cows took together twenty-seven pounds daily, for three months, with impunity; and two fat cows took in addition

nine pounds of ergot daily," with no ill effect whatever.

The same conflicting statements are made as to the effects of ergot on man in health; some affirming that in doses of half a drachm to two drachms it excites nausea, occasions pain in the head, dilated pupils, &c.; while other experimenters declare that it produces no effects whatever. This is probably the fact; since we have heard of only some very rare cases in which it has had any other effect upon the susceptible pregnant, or parturient female, than that of exciting uterine contractions. We may, therefore, conclude that the fractional number of some five or six cases in which delirium or stupor is said to have resulted from doses of half a drachm to two drachms was due to other causes; especially when it is considered that such affections of the head are not unusual with parturient women where no ergot has been exhibited.

Universal and large experience has settled the fact that ergot has no special influence on the nervous system, and that, in its therapeutical doses, at least, it is perfectly inoffensive when administered with the proper "precautions" that are relative to the uterine system. This consideration, therefore, imparts an inestimable value to the uterme agent; and the other attending circumstances go with iodine, arsenic, &c., in reprobating all conclusions as to the therapeutical virtues of any agent which are associated, as inductions, with its manifestations upon man in health, and especially upon the modified constitution of animals, or the yet greater modifications that are presented by vege-There is no other agent known to possess virtues analogous to those of ergot, while, also, its only manifest influences are pronounced under special modified states of the uterus. But, perhaps you say, and truly, too, that other things will excite abortion, or sometimes hasten natural labor. But, in all such cases, the results depend on very different influences; on some violence inflicted on other parts, or some uterine or other malady which may be thus removed. Cantharides may have sometimes excited abortion; but, if this be true, it is practically useless, rare in the effect, and obnoxious to other palpable objections. The highest practical as well as philosophical considerations are every where involved in the principles now, again, under investigation (§ 137 d, 143 c, 150, 151, 650, 831, 836, 854 bb, 857, 859 b, 892 c, $892\frac{1}{2}$ b, &c.).

 $892\frac{5}{3}$, d. The next question which comes up relates to the circumstances under which the uterus is susceptible of the influences of this specific agent; for this *one* may be so regarded till others may appear

which will accomplish the same results.

Such is the remarkable action of ergot after labor has been instituted, especially after the usual period of gestation, that it was natural, perhaps, to suppose that the agent can bring on the process by its own specific virtues (§ 143 c, 150, 151, 652 c, 863). Experiments have been accordingly made upon animals to ascertain whether abortion would be thus brought about; but Villeneuve, Warner, Chatard, and

others, have failed in all their attempts, whether the ergot be injected into the circulation, or administered by the stomach (§ 150, 151). But this would not prove that abortion may not be thus instituted in the human subject (§ 892\frac{2}{3}, c). And to show how deeply founded in nature are some of the important laws embraced in a former section (§ 150), it is worthy of remark that ergot commonly promotes the uterine contractions in dogs, cats, sheep, cows, deer, and, indeed, of all other animals, so far as tried, after natural labor has been for some time in progress; even where the uterus has become exhausted by its long-continued efforts.

As to the human female, there is probably not much doubt that ergot is capable of exciting abortion. The vital relations, in the pregnant state, are more or less in correspondence with the virtues of the agent (§ 143 c, 150, 189 b, $892\frac{2}{3}$ c). The question is stated in the following manner by an adequate observer, and who believes in this

remarkable virtue of the great uterine agent:

"Given," he says, "to excite abortion, or premature labor, ergot has sometimes failed to produce the desired effect. Hence many experienced accoucheurs have concluded that for this medicine to have any effect on the uterus it was necessary that the process of labor should have actually commenced. But, while we admit that it sometimes fails, we have abundant evidence to prove that it frequently succeeds." Other able observers testify to this fact; Müller, Ramsbotham, and other familiar names.

It is evident, too, that ergot is capable of acting upon the uterus, and of exciting contractions of the organ, in its unimpregnated state, when its susceptibilities are increased by disease (§ 143 c, 150, 151, 177, 189 b). Uterine polypi have been thus expelled, and menor

rhagia arrested.

But, this ceases to be remarkable when it is considered how greatly changed is uterine irritability in a state of pregnancy; when the most trifling causes, such as lifting a chair, putting up window-curtains, sudden joy, sudden surprise, or grief, will rouse the muscular action of the impregnated uterus, and bring on abortion (§ 150, 151, 189 b, 227, 233, 233\frac{3}{4}, 904 d). If we now add to the foregoing considerations the increasing tendency to abortion in proportion to the frequency of its occurrence, it may aid our philosophy of life in its general aspects, and concur with other facts in a specific illustration of what I have propounded as to the laws of vital habit (§ 535-567).

Our experimental knowledge, however, as to the ability of ergot to institute labor must be always limited; for opportunities must be rare in which a physician of any moral sense, and therefore of any reliable truth, would administer this, or any other agent, with a view to producing abortion. Even in the very limited number of cases where art is called upon for this solemn duty it rather seeks the me-

chanical method.

Connected with the difficulty of attaining an adequate knowledge of the power of ergot of inducing abortion (especially the extent of its power), are the numerous mistakes that have been made in respect to other supposed effects of this substance; particularly those which are relative to the epidemics, and which continue to be more or less ascribed to its malign influence. But, what is more to the present purpose is the important fact, that, although now as in the "epidemic"

times (p. 622), doubtless, rye largely compounded with ergot is habitually and very extensively consumed, we have never heard, as one of its evil consequences, that it has given rise to abortion. This undeniable truth, therefore, must settle the question, at least, as to any uniformity in this imputed effect of ergot, and turn our attention to the mechanical means when the interposition of art is required, and our scrutiny to other expedients in detecting the criminality of others. A right decision of the question is one of great interest, not only in a philosophical aspect, but on account of its practical bearings, and, also, in a medico-legal aspect.—Note A p. 1111.

8923, e. It may now be said to the young practitioner, that he should bear in mind that the expulsive efforts are made by the uterus, that all the devices of the lying-in chamber, such as straining, pulling, &c., are worse than useless, that the uterine contractions are increased in violence and frequency soon after the administration of ergot, and that they generally go on increasing till the birth is effected. Indeed, the parturient process sometimes continues, under the influence of the agent, for several minutes after the expulsion of the pla-

centa; but it commonly ceases, so far as the ergot is concerned, after delivery is consummated (§ 150, 151, 652 c).

 $892\frac{2}{3}$, f. The rapid and energetic action of the uterus led Dr. Stearns to say, that, among other things, it is "of the utmost consequence to ascertain whether any preternatural obstruction prevent the delivery;" and, from what is also said of the circumstances which justify the use of ergot, it is evident that the discoverer considered a full dilatation of the os uteri of indispensable importance to any thing like a safe result. He foresaw that the uterus might otherwise be ruptured, or the external parts lacerated, or the child destroyed by the rapidity with which its head would be forced along the yet rigid parts. He foresaw, I say, a violation of nature if the foregoing condition were not awaited. And how fearfully has this been verified in practice; especially as it regards the fœtus! Why the vast difference in results in the hands of different accoucheurs? Why the numerous cases of cerebral hemorrhage in still-born children, that have come up, of late, for the good of science? The question is readily expounded when we turn to those Essays in which it is affirmed that ergot may be administered when the mouth of the uterus has attained the diameter of half an inch! This has been recommended principally with a view to saving the time of the practitioner; and it opens to us the ground of the prejudices, which have sprung up in enlightened and more honest quarters, against the use of ergot when it can be possibly avoided. Where the safety of the mother does not require earlier interference, it is, doubtless, a good rule not to administer ergot till the head of the child has passed the brim of the pelvis, and the labor has become lingering.

If the remedy be delayed till the os uteri is well dilated, then, by an admirable concert of sympathy, the external parts will have either undergone a corresponding dilatation, or a tendency to an easy dila-

tation (§ 150, 151, 385, and references).

8923, g. "Previous to the exhibition of ergot," says the discoverer, "it is of the utmost consequence to ascertain the presentation;" and now the only question that arises is relative to the admissible presentations. The os uteri is, of course, supposed to be fully dilated; and it

appears to be conceded that ergot may be employed when the head is turned from its usual position. But, this is not auspicious. Breach presentations admit of its use where labor has become prolonged, and the pains suspended; though here manual aid may be safely applied without the forceps. These instruments are always difficult but in the hand of experience, and are otherwise more or less liable to ob-

jection.

 $892\frac{2}{3}$, h. It is not alone in protracted labors, where the uterine efforts have ceased to be efficient, that ergot is applicable with a view to promoting delivery. Serious hemorrhages sometimes spring up, where it becomes important to hasten delivery by every possible means that may be less hazardous than the impending evil. In cases of this nature, especially when alarming hemorrhage comes on during natural labor, and the attachment of the placenta is right, we enjoy no means so likely to insure safety and immediate success as offered by ergot; so only the pelvis be not deformed, and the presentation suitable.

8923, i. So, also, in ordinary cases of abortion, where hemorrhage may become alarming, ergot may be employed to hasten the expulsion of the ovum, and arrest the flow of blood. In these instances, however, the tampon is probably preferable, since it is always sure,

and it is not certain that abortion will happen.

892², k. Some females are remarkably liable to profuse uterine hemorrhage after natural labor; and these are cases for the administration of ergot a few minutes before the expulsion of the child; whatever may be the activity of the uterine contractions. In such instances it is not unusual for the pains to be quite energetic throughout the labor, but to cease abruptly as soon as the child is born. The advantage of ergot, therefore, administered some fifteen or twenty minutes before birth takes place, consists in its disposition to maintain the uterine contractions till the organ is so reduced in volume that hemorrhage is prevented or arrested.

 892_3^2 , \tilde{l} . Again, where the forceps cannot be used in puerperal convulsions, ergot may be rendered a valuable substitute. The objections which have been made to its use in this condition, on the ground of its tendency to affect the head, appear to be hypothetical. In any thing like its therapeutical doses, the common experience of mankind has fully settled the fact that it has no tendency to induce or to increase cerebral or any other condition of disease, excepting as it may increase

convulsions sympathetically through its uterine influences.

The erudite Pereira, in his Materia Medica, pauses over the exhibition of ergot in puerperal convulsions, because, as he says, "The narcotic operation of ergot presents a serious objection to its use in cere-

bral affections" (\S 960, a).

There existed a remarkable prejudice against ergot throughout Great Britain, for many years after it had come into extensive use in other countries, on account of the stories about its having produced wide-spread epidemics at former periods. Indeed, it was not employed, I think, in England, till the year 1824, or about sixteen years after it was in successful use in America. Some of the old prejudices remain in Great Britain, and where they exist the risk of that formidable affection, puerperal convulsions, will be taken sooner than one of its most efficient means of relief will be employed. We need not inquire, in the foregoing cases, whether the os uteri be dilated, so

only labor have fairly begun. But, we may not precipitate ourselves at once upon ergot. There is something else to be done first. The patient, I say, should be first thoroughly bled, as a preliminary requisite, not only on account of the cerebral affection, but to place the whole genital organism in a most favorable state for a ready expulsion of the child. Let each remedy come in its appropriate place. A violation of their proper order of sequence may be fatal, and doubtless has been (§ 960, a). The specific, as it is called, is, or should be, often the last in the consecutive series. If cerebral disease be not first moderated by loss of blood, the increased uterine irritation occasioned by ergot cannot fail to increase the evil in the head of which it had been the sympathetic cause. But, loss of blood strikes both at cerebral and uterine disorder. Nor have I any doubt that, where any cerebral symptoms have sprung up after the employment of ergot in its therapeutical doses, they have been due either to entirely different causes, or to the use of the agent at so early a stage of labor that an injurious violence has been inflicted on the uterus, and thus sympathetically upon the nervous centres (§ 230). There has been great rashness in the use of ergot, from an unnatural haste of some practitioners to get rid of their patients in one way or another. It is this haste which I would reprobate, as, also, a careless administration of ergot without a due reference to a proper state of the local requisites, and its employment in such excessive doses as render uterine action injuriously violent (§ 878). In such instances, we need not be surprised at any untoward result; and, if the uterus be ruptured, or the child destroyed, or the nervous system shaken at its centre, we may not blame the remedy.

8923, m. In cases where the placenta is retained from want of proper uterine contractions, ergot, if employed soon after the birth of the child, rarely fails of its purpose. The longer, however, its administration is delayed, the less likely will it be to reproduce the uterine contractions. Nature has accomplished her great purpose after the expulsion of the child; and if, from artificial influences upon the human constitution, she pause at her remaining office, it may often be that she is prematurely started upon her recuperative process, in which she now makes all haste to her wonted station. But, whether so or not, experience assures us that uterine irritability undergoes changes very rapidly after the expulsion of the fœtus, and that, in the same ratio, the reflected nervous influences induced by ergot fail of

acting upon the muscular tissue of the organ (§ 150, 151).

892²₃, m. Where retention of the placenta depends upon spasmodic action of the uterus, or is owing to morbid adhesions, ergot yields no benefit, and may be injurious. The former condition certainly constitutes a serious objection to its use. The reason is, that one part of the organ is now in a more irritable state than the rest, and ergot, therefore, will act with unequal effect and increase the spasm; just as a cathartic will increase spasm of the intestine which depends upon some inflamed portion of the mucous tissue of that organ (§ 150, 151).

 892_3^2 , o. Our parturient agent has shown itself capable of arresting uterine hemorrhage in the unimpregnated state, and that it is a useful agent in menorrhagia. Here it displays another attribute, and yet another differing from the astringent virtue. It does not now act as in the foregoing cases, as is evident from its failure of inducing any

of the phenomena of uterine contraction, while, moreover, the uterus is already in its contracted state. Its effect, in these cases, is like that of common salt, or of ipecacuanha, in restraining hæmoptysis. That is to say, of the individual substances, each one exerts some change in the action of the part peculiar to itself, but differing more or less from that of astringents, by which the secretion of blood is arrested (§ 904 d, 890, a).

Again, it is said that ergot has been successfully employed in hemorrhages from the stomach, intestine, lungs, nose, and gums; all of which concurs in farther illustrating the modus operandi of the pure astringents, and of ergot in restraining menorrhagia. It should be added, however, that the anti-hemorrhagic effect of ergot, except 28

it respects the uterus, has been overrated.

 $892\frac{2}{3}$ p. All the foregoing effects of ergot, from its excitement of uterine contractions to its restraint over hemorrhage, are demonstrative of its operation through reflex action of the nervous system, and, with a multitude of other things which I have brought to the attention of the reader, supply a ground of analogical induction as to the modus operandi of all other remedies (§ 893½).—Note A, on the cause of Labor.

EMMENAGOGUES.

 $892\frac{2}{3}$, q. In the foregoing sections I have been so near upon emmenagogues, and as the right treatment of amenorrhea concerns so nearly a vast number of important cases, I shall briefly state the results of my own observation in connection with this subject, and with a view, also, of multiplying illustrations of the principles which form the ground-work of these Institutes.

Emmenagogues are arranged in my Materia Medica under the general denomination of Uterine Agents, of which ergot is the first, cantharides the second, and guaiacum the third in importance. I dropped the usual denomination which appears in this section, partly with a view of moderating a common belief that suspended menstruation is to be always treated by some agent bearing the name of an emmenagogue, as the name chlorosis leads to medication of the blood.

All the agents comprised in this group possess virtues that exercise, more or less, extensive though various influences upon the uterine system. In consideration of this known relation, such of them as have received the appellation of emmenagogues (of which cantharides and guaiacum are the principal) are apt to be employed with a reference alone to the prominent symptoms attending amenorrhæa. But, when the failure of the uterine function stands by itself, all the emmenagogues may be inapplicable on account of some special morbid state of the uterus upon which the cessation of the discharge de-They are always contra-indicated, cantharides and guaiacum especially, in all inflammatory and irritable states of the uterus; at least, till these conditions are overcome by antiphlogistic means They are also inadmissible where menstruation is only suspended by some direct influences, as from exposure to cold, &c.; and they are positively injurious where the suspension depends upon sympathetic influences propagated by some active form of disease in other organs.

8922, r. In a large proportion of cases amenorrhæa is consequent on chronic maladies of the chylopoietic viscera, when uterine remedies are often administered with reference to the remote consequence; and the condition of the important organs in which the uterine embarrassment had its origin, and by which it is commonly maintained, is apt to be overlooked or neglected. Where, however, the abdominal derangements are sufficiently pronounced to attract attention, it is not less common to look upon these primary causes as the results of a mere failure of the uterus to excrete its natural product. This interpretation comes of the humoral pathology, and is one of the every-day

practical illustrations of the amount of its philosophy.

But, menstruation has a totally different final cause than humoralism imagines (§ 428-432). The evils which are imputed to a failure of the evacuation depend but little upon this circumstance. They are due, on the contrary, to the morbid state of the organ through which the excretion fails; and this condition is various in its pathological nature. According, also, to the pathological state of the uterus, other things being equal, will be the nature and amount of its disturbing reflex nervous influences. In a large proportion of cases, however, the uterus suffers but little, and its function returns as soon as the remote influences are overcome.

Hence, it is obvious that the main treatment should be addressed to the organs of the abdomen in all the cases included in this section. The state of the uterus, it is true, reacts upon the primary and leading seats of disease; but generally feebly (§ 905, a). Local means should, therefore, go along with the more constitutional ones; such as leeching the perineum, exercise on horseback, the hip-bath, &c., ac-

cording to the general nature of the case.

 $892\frac{2}{3}$, s. The foregoing view of our subject inculcates a variety of treatment in the multifarious aspects of amenorrhæa, and regards all things as emmenagogue, in principle, which will restore the uterine function; though that be commonly one of the least important effects. A cathartic may be best when menstruation is suddenly arrested by exposure to the cold, or a hot bowl of motherwort may do as well. Bloodletting is the main remedy when amenorrhæa is owing to inflammation or congestion of the uterus, whether it be primary or secondary. Exercise in the open air, especially on horseback, chalybeate tonics, mercurial and aloetic laxatives, a well-regulated diet, &c., are the means when it is dependent on indigestion (§ $892\frac{1}{2}v$).

8922, t. Having accomplished the leading intentions in the chronic forms of amenorrhea, if the uterus still fail of excreting the menses, those agents which are known as emmenagogues may then be called into use; and of these, cantharides, administered till slight strangury takes place, is not only the most efficient, but far the safest. Guaiacum is liable to irritate the stomach injuriously, and to stimulate, unfavorably, the whole system, and especially the uterus. There are many cases, however, in which the uterus may ultimately require this peculiar irritation, or where certain states of constipation will yield, happily, to the action of guaiacum; but they require a sounder reference to the exact condition of the organ than when cantharides is employed. The uterus, indeed, is so liable to an interruption of its menstrual function that slight degrees of indigestion will occasion its failure; and in these cases cantharides will generally be entirely compatible with the abdominal affection, and sufficient in itself to re-establish menstruation. This variety of things leading to a specific result can be expounded only through alterative reflex actions of the nervous system (See GENITO-URINARY AGENTS, p. 683-689).

DIURETICS.

892\frac{3}{4}, a. Diuretics are agents which increase the urinary discharge, and are employed either for that purpose specifically, or more commonly with an indirect reference to dropsical affections, upon which they are supposed to operate by promoting the absorption of the fluid

and its excretion by way of the kidneys.

 $892\frac{3}{4}$, b. On looking over this group of remedies, it will be at once seen that it is obnoxious to objections which I have made to other groups, and that, as in the former cases, the denomination of diuretics must be received with special qualifications. Many remedies, also, are not embraced in the group which are capable of producing, under particular circumstances of disease, the most powerful diuretic effect. This is especially true of cathartics, and of some of them to so great an extent as to have procured for them the appellation of hydrogogue cathartics, or such as are capable of expelling dropsical effusions. Indeed, I may say that cathartics are better entitled to the name of diuretics than any other group of remedies; since no one of them operates upon the intestine without very generally increasing the excretion of urine; and, as to their relative effect in subduing dropsical affections, they greatly surpass the diuretics proper. The latter agents scarcely extend their influences beyond the kidneys; while cathartics accomplish their work as diuretics by overcoming the diseases upon which dropsical effusions depend, and by thus, also, withdrawing morbific reflex nervous actions which those or other diseases inflict upon the kidneys, and, thirdly, by exciting the kidneys to a freer production of urine ($\sqrt[6]{227}$, 422 b, 423, 516 d, no. 6, 524 c, 889 a, 891 $\frac{1}{2}$ k, 892 $\frac{1}{2}$ k, t).

These remarks relative to cathartics lead me to advert to their control over dropsical affections as one of the demonstrations that dropsy depends upon inflammatory conditions. That pathological cause being removed by the antiphlogistic virtues of cathartics, the redundant effusions cease. The modus operandi is shown in the last references.

Bloodletting, which is not among diuretic remedies, has often as great an effect as cathartics, often greater, in establishing a copious production of urine, where it has been greatly diminished or suspended. And, from what was just said of the pathology of dropsy, it should be the best remedy, as it certainly is, in the early stages of hydrothorax and ascites.

To exemplify yet farther the nature of diuretics, and whether one thing or another will determine an increased flow of urine, and to show that this is an insignificant result of all the agents that may be employed, and that it is to the seat and pathology of disease that all our prescriptions should refer,—keeping the attention there and away from the kidneys,—I may refer to what was said of the diuretic effect of iodine in a former section, and of its modus operandi in subduing dropsy (§ 892½, k, t. Also, last references).

Again, there is nothing more uniformly and powerfully diuretic than fear, which, in all its degrees and modifications, rarely fails to increase the urinary product; being, also, in its excessive operation, a most powerful sudorific, while it simultaneously determines the blood from the circumference to the centre. The boldest warrior is not without the universal instinctive principle which impels all animals to flee from danger. On the eve of battle, when most stimulated by

pride and the hope of victory, he shows that another principle is in powerful operation by the frequency with which he dismounts, or turns aside from the ranks, to let off troublesome accumulations of urine. And just so with man whenever dangers impend; whether they threaten his life, his limb, or his reputation. And so with any event in the success of which he has an immediate interest. All this, too, is equally true of animals; and it all conspires in showing that humoralism, and "dynamic" and "quantitive" chemistry, are upon the wrong track, and that as mental emotions can excite diuresis and perspiration only through direct nervous influence, so do physical causes by reflex nervous action upon the secerning vessels (\$ 422 b, 1067).

But, there is a vast variety remaining of the foregoing nature. Take a modification of fear, as showing the delicate shades of difference among the passions, and how they correspond in their effects, and in their organic influences, with material agents. Thus, anxiety, which has fear for one of its elements, exerts, also, a like but modified effect upon man. So, again, jealousy, which results from the united opera-

tion of fear and love (§ 1881, d). Thus Sappho:

"In dewy drops my limbs were chilled, My blood with gentle horrors thrilled, My feeble pulse forgot to play, I fainted, sunk, and died away."

And, coming to the pure element, love itself, we observe other coincidences with fear; especially as it respects perspiration. In excessive joy, also, we meet with another powerful diuretic, as, likewise, in the sympathy between man and man. But it is manifest, in all these cases, that each agent, each passion, produces influences peculiar to itself, each one in its individual or its compound aspect. It is variously illustrated in the following sections: 227, 228 b, 233\frac{3}{4}, 234 e, 500 c, g, k, n, 512, 652 c, 827 c, 828 a, 844, 902 g, 904 d, and in other places; while it may be said, in respect to the passions, that we may discern in the different conditions of the perspirable matter, and in the different states of the skin, indications of different organic influences that are exerted by the nervous power, and carry the same conclusions to other parts which may be impressed in their organic states (§ 227, 228 a, &c.). The same is true, also, of those emotions which are awakened by physical influences. Certain odors prove diuretic to some and cathartic to others; and, as affirmed by Shakspeare,

> "—— others, when the bag-pipe sings i' th' nose, Cannot contain their urine for affection. Masterless passion sways it in the mood, Of what it likes or loathes."

The last is analogous in its philosophy to what is said of light in section 514, l. And as to offensive sounds, which fall under the same category, it is related by Dr. Fairfax that, "Mistress Raymond, whenever she hears it thunder, even afar off, begins to have a bodily distemper seize her. She grows faint, sick in her stomach, and ready to vomit. At the very coming over of the thunder, she falls into a downright cholera, and continues under a violent vomiting and purging as long as the tempest lasts. And thus hath it been with this gentlewoman from a girl." Beddoes speaks of analogous results. "At any moment," he says, "inflammation may be kindled in any part by some causes which we cannot distinguish; by others too subtle for

our senses, as, perhaps, by a thunder cloud passing over head" (§ 230, 828 c). Until the nature of lightning was understood, it was supposed that it corrupted the blood in such cases. But, later "experimental philosophy" has enabled the chemist to expound it in another way, and to the easy comprehension of most people (§ 349, d, e), while the few take a more circuitous method (§ 222–233 $\frac{3}{4}$, 500, 893–905), although at no little peril (§ $5\frac{1}{2}$, a). Again, cold, applied suddenly to the surface of the body, is often a powerful diuretic (§ 422, 423). But, although neither this nor the preceding causes are ranked as diuretics, they are probably about as much entitled to this designation as those agents to which it is specifically appropriated (§ 844).

 $892\frac{3}{4}$, c. The agents and causes of which I have now spoken disclose the whole philosophy of the operation of such as are especially denominated diuretics, and place it mainly upon the ground of direct

and reflex actions of the nervous system.—Note D p. 1114.

Whether, therefore, it be loss of blood, or cathartics, or cold applied to the surface, or the operation of fear, or other mental emotions, which increase the excretion of urine, they all do it by acting directly or indirectly upon the secreting vessels of the kidneys, and mostly by means of direct or reflex nervous action. Loss of blood may be directly exerted upon the organs, or it may be, as is generally true, through the instrumentality of the nervous system, by removing disease from some other part, as the liver (which is a common example), and which had sympathetically diminished the excretion of urine. The principles, as it respects the nervous power, and the change of organic actions, are the same with cold, fear, &c. Coming, lastly, to the diuretics proper, such as are truly remedial produce their effects, also, upon exactly the same principles (§ 277). Nevertheless, it is undoubted that certain substances of mild remedial virtues, especially such as are not offensive to the lacteals, or to the general organism, gain admittance more or less readily into the circulation; and, coming in contact with the kidneys, may stimulate, and increase the action of, these organs. Such, for example, are certain neutral salts. Probably the acetates of potass and soda may produce their effects upon the kidneys more or less in this way; though certainly, also, through the nervous influence when they prove cathartic. In respect to these two agents, however, the chemical and humoral theorists are not all satisfied with their general hypothesis (§ 278).—Note Z p. 1130.

Nor is it at all surprising that the functions of the skin and kidneys should be so readily affected by the nervous influence, as developed by the foregoing causes, mental and physical, when we consider the final causes of each of the organs, and that Nature has ordained for their fulfillment a great versatility of action, and that, therefore, morbific and remedial agents will operate variously, according to their several virtues, through that natural constitution of the organs (§ 423 513, 902 f, g). This consideration also lets us into the reason why the urine flows so abundantly after some fluids, such as gin (which contains the diuretic juniper), and in some cases before there can have been time for their incorporation with the blood; a fact, indeed, so often observed, that many physiologists have supposed that there must be some more direct communication between the stomach and bladder than by the ordinary route of the absorbents (§ 350, no 94).

 $892\frac{3}{4}$, d. The "diuretics proper" are the least useful of all the an-

tiphlogistics; having but little effect upon inflammations or fevers. Yet are they often prescribed in high grades of those affections (where the urine is greatly deficient), in the vain expectation of reaching those profound lesions by the removal of one of their least important sympathetic consequences. Their use, however, with the more enlightened, is now mainly limited to dropsical effusions in the great cavities and the extremities; however defective may be the pathology, or however inefficient these agents are compared with bloodletting, cathartics, blisters, mercury, iodine, &c. They are always most useful in cases that are benefited by loss of blood and by cathartics (See as to heart in \S 500 m, $685\frac{1}{2}$, $687\frac{1}{2}$, $694\frac{3}{4}$, 826 cc).

8923, e. Some of the diuretics which possess compound virtues, such as squill, and Indian hemp (apocynum cannabinum), may prove very detrimental in many cases of dropsy; the former, for example, by its acrid, stimulating virtue, the latter by its severe action upon the intestinal canal. Where mercurial agents are employed, they should be well chosen, and according to the existing pathological states. In the simple form of dropsy, or if inflammation exist in any degree of activity, as in the serous tissue, or in the liver, then some one of the simple mercurials should be selected, as calomel, or blue pill; preceded, however, by loss of blood, &c. If, on the other hand, the dropsical effusion have existed a good while, or be attended by chronic enlargement of the liver, or of some other viscus, the mercurial should be chosen with reference to such organic affections; though calomel or blue pill may answer well. But, in these cases, the iodides and bromides of mercury are the most appropriate; and now we may, sooner or later, employ squill with or without other diuretics, though it is commonly most useful to combine two or more together. If the subject be of a scrofulous habit, iodine should be used freely.

8923, f. Much has been said of the connection of renal disease with dropsy, and many physicians have, in consequence, gone into a chemical analysis of the urine, instead of the signs to be observed in the body, for an exposition of the nature of disease. But, so many coincidences have sprung up from other causes, that it may be expected

that this "experimental philosophy" will not endure.

892\frac{2}{4}, g. The greatest of all the errors in relation to dropsical affections is that which divides them into active and passive. This error appears to have grown out of another—that which makes the same distinction of inflammations (\sqrt{52}, &c.); though, in the former case, the relative states of pathology are supposed to be in even greater opposition. The practice proceeds upon the same hypothesis as that which concerns the distinctions in inflammation.

EXPECTORANTS.

 $892\frac{4}{5}$, a. This group of agents has had too large a connection with disease to be neglected; or, at least, not to be k 1d responsible for any mischief it may have done. Like many other denominations, the term is significant of their most visible effect, although, like many others, it is one of the least important in a large proportion of the diseases where they are employed, while the most important can be obtained only by remedies that do not fall within the group.

The tendency of the name, and the definition which is given of expectorants, have turned a great amount of attention upon the quantity

of matter expectorated, and away from those pathological conditions upon which the physical product depends (§ 889 c, 891 d, o).

It is greatly, therefore, with expectorants as with sudorifics, diuretics, &c. The secreted product is only a secondary result; complicated and various in respect to the conditions and influences by which it is brought about, and capable of being increased or produced, under different vital states of the body, by agents of entirely opposite virtues,—by the most direct sedatives, and by the most active stimulants. Every thing, therefore, which will, under any contingencies of disease, increase or produce expectoration, is more or less entitled to be considered an expectorant. Hence, it is apparent that, whenever remedies are applied with a view to the supposed objects of expectorants they are quite likely to aggravate formidable grades of disease, or to leave the subject, at least, to an unresisted fate which might have been

averted by appropriate means.

892\(\frac{4}{5}\), b. In my Arrangement of the Materia Medica, I have placed some agents, under the denomination of expectorants, as first in importance, which others, who consider mostly the result upon which the group has been founded, would rank lower down. But, as the foundation of my arrangement relates to the therapeutical capabilities of the various substances, I have designated tartarized antimony as the first, and ipecacuanha the second in importance. These agents, in a general sense, are most useful under the condition in which expectoration is desirable, if relief be not obtained without; though it may or may not be a result of their action. It is now, as when sweating may take place profusely, moderately, or not at all, from what are denominated sudorifics. But, I should say that the parallel does not hold strictly in these cases; since the sympathies between the stomach and skin are so far different from those which prevail between the stomach and the lungs, that mild impressions made upon the stomach, as by hot water, will determine profuse perspiration, or, as in other cases, irritating food will occasion, speedily, eruptions of the skin; while none but agents of considerable power will institute reflex nervous actions in the lungs, or give rise to that expectoration which grows out of such actions. All the expectorants, therefore, of any importance are capable of exerting powerful effects, either for good or for evil; while, of all the sudorifics, tartarized antimony and ipecacuanha are the only ones that are entitled to consideration on account of the alterative reflex nervous actions instituted by expectorants.

Reflex nervous actions, as excited by the operation of agents upon the stomach, depend not only upon the nature of the agents, the natural function of the sympathizing part, and the particular mode in which it may be affected by disease, but upon the analogies that may subsist in the structure and vital constitution of the mucous tissue of the stomach and the part remotely influenced (§ 133–152, 525–529). The group of remedies now before us refer to a tissue of the same species as that of the stomach upon which the remedial agents exert their direct effect; and reflex nervous actions upon the pulmonary mucous tissue, when induced by remedial agents applied to the stomach, are, for this reason in part, different from such as are exerted by the stomach upon the skin, and are generally much more profound, and of a more alterative nature.

8921, c. The effect of remedies, therefore, in their acceptation of

expectorants, being determined by the existing condition of disease, and more or less by the state of the system at large, and conditions not much allied admitting the agency of remedies that operate as expectorants, it is clear that we must have a classification of these remedies according to their general virtues. I have, therefore, more or less after the manner of others, distributed them into five subdivisions. These I shall now state, along with the several agents embraced under each subdivision; and, for the purpose of illustrating my conceptions of their relative bearing upon disease, and with only a secondary view to the expectoration which they may be, respectively, capable of producing, I shall designate each one by numbers that denote their order of arrangement, and their relative therapeutical uses where expectoration is a desirable consequence if the remedy do not succeed without.

Non-stimulating.—1. Potassæ antimonio-tartras. 2. Cephælis ipe-

cacuanha. 4. Gillenia trifoliata. 6. Asclepias tuberosa.

Stimulating.—3. Scilla maritima. 7. Polygala senega. 8. Dorema ammoniacum. 10. Opoponax chironium. 13. Eryngium aquaticum. 14. Myrospermum toluiferum. 15. Myrospermum peruiferum. 16. Naphthaline. 17. Styrax benzoin. 18. Styrax officinale. 19. Liquidambar styraciflua. 20. Amyris gileadensis. 21. Allium sativum. 22. Erysimum alliaria. 23. Sisymbrium officinale.

Stimulating and Narcotic .- 5. Sanguinaria canadensis.

Sedative and Narcotic.—11. Lobelia inflata.

Stimulating and Antispasmodic. - 9. Ferula asafætida. Ferula

persica. 12. Galbanum officinale.

It will be seen, therefore, from the foregoing general distribution of expectorants, that four of them only are adapted to any thing like acute inflammation of any tissue of the lungs; and that the first two only are wanted. Moreover, none of the expectorants are employed as such excepting in some inflammatory state of those organs; or, at least, according to my views of all the pathological conditions for the relief of which the expectorants are intended. And when it is considered, also, how very irritable and susceptible the lungs are when affected in their parenchymatous structure, and even those parts of the mucous tissue which line the bronchi, larynx, and trachea; how liable, too, inflammation is to be propagated from the upper portions into the air-cells; how many there are in whom pulmonary phthisis is readily awakened by inflammatory states of this membrane; how they constantly throw morbific influences over the stomach, the intestine, the general organs of circulation, &c.; and how often inflammation of the tracheal portion of the membrane eventuates in ulceration; besides other sequelæ of inferior moment; it becomes apparent that this group of remedies, with the exception of the two leading members, has numbered its victims next after those agents which form the groups of tonics and stimulants.

Why, then, it is asked, perhaps, does the squill rank, in the arrangement, as the third in therapeutical value, and before the non-stimulant American ipecacuanha, bloodroot as the fifth, seneka the seventh, gum ammoniac the eighth, and these last three before asafetida, &c.? The answer is important, although the order of arrangement assumed that the reader was sufficiently conversant with the principles upon which it is founded. It assumed, in the first place, that he was famil-

iar with the general structure of the lungs, that he had some ideas about a "chemical" difference, at least, in the relations of different portions of the pulmonary mucous tissue to this group of remedies (§ 134-143); that he was aware of the inflammatory nature of the disease for which he was prescribing, as well as its exact seat; that he distinguished between acute and chronic forms of inflammation; that he understood, that, as one portion or another of the pulmonary mucous tissue might be the seat of disease, and according to the special modification of disease, it might be relieved or increased by different expectorants, and according, also, as the premises might be, he foresaw that this or that expectorant might develop tuberculous phthisis, or become the indirect cause of disease in other parts, &c.

Proceeding, therefore, upon these principles, and as chronic inflammation of the mucous tissue of the trachea and bronchi is a very common form of disease, and is often benefited, in constitutions that are otherwise sound, by a stimulating expectorant, it was important that some one, at least, should occupy a high place in the Arrangement. But, it should be also one whose virtues are most of an alterative nature, but most exempt from morbific tendencies; whence it becomes plain that the scilla maritima should stand immediately after the cephælis ipecacuanha. It should also precede the gillenia, since the virtues of this last, as, also, of the asclepias, are analogous to those of the great product of Brazil, yet much inferior. But, comparatively unimportant as the gillenia and asclepias may be, they are yet so analogous to ipecacuanha, that they may stand by its side, and being of easy access to the American practitioner, they should follow near upon the other two non-stimulant expectorants; gillenia taking the precedence of the asclepias on account of its greater alterative virtues.

Asafetida, I am aware, is a favorite expectorant with many; but it is less alterative than seneka, and the preceding gums, and is much

more liable to offend the stomach.

As to bloodroot, that substance stands, like castor oil, alone in the Materia Medica. It is capable of peculiar influences; but, as they are oftener injurious than beneficial I have given to it a higher rank than was warranted by my own experience or by that of some others. It has been, however, highly commended; and in deference, therefore, to that more favorable experience, it appeared to me that it should occupy a place in the Arrangement that might yield to the remedy a fair opportunity for more ample observation of its effects,

so far as my Arrangement might have any influence.

The foregoing analysis will serve, also, for the disposition which I have made of the members of all other groups. The arrangement bears upon its face the author's conceptions of their special relations either to pathological conditions that are most allied, or to such as are diverted from the common forms, or to others which are distinguished by greater peculiarities; while, also, the order of each one, under the various assemblages, denotes its therapeutical capabilities. If the author, therefore, be right in his premises upon which the arrangement is founded, each article is thus rendered more or less descriptive of its own uses, &c. (§ 892, aa, c).

8923, d. There should be no difficulty with correct observers in reaching a knowledge of the conditions of disease to which remedial agents of such various and even opposite virtues as the expectorants

are adapted. The general principles of pathology and therapeutics go far in indicating, at once, which of the groups are properly suited to certain pathological states, which of its members is best adapted to any modified condition of the general pathology, or which of the groups, or which members of the proper group, should be avoided. But, a nice discrimination of the variously-modified forms of inflammation, whether as to its nature, intensity, duration, complications, &c., and a precise acquaintance with the peculiarities of each remedial agent, will be often necessary to guide us to the just regulation of influences which any given combination of symptoms may demand; or, proceeding blindly to execute the results of an expectorant, in its ordinary acceptation, and under the belief that each substance so denominated will alike fulfill the intention, we may as readily destroy the patient, in the end, by this indiscriminate practice, as we might, with certainty, relieve him by a choice of other means bearing the same general name of expectorants. It is not, therefore, I say, the abstract fact of expectoration that we are to regard, but this is to be considered as a result of a favorable action which certain remedial agents are capable of instituting, but which very often fail of that result when their action is in the highest degree salubrious. On the contrary, also, we shall see that expectoration may be increased by increasing the morbid conditions; just as the discharge of mucus, in intestinal inflammation, is increased by an irritating cathartic. The only difference consists in the direct action of the morbific irritant upon the affected part, in one case, and by reflex action through the nervous power, in the other (§ 150, 151, 226, 228, 229). It is, therefore, far from being true that the remedy is appropriate when the discharge from the lungs is promoted and increased, even though an expectorant be especially indicated, and the proper one may also tend to lessen the quantity of mucus through such alterative influences as lessen the morbid action upon which it depends.

8924, c. We see, therefore, more and more, how indispensable it is to look upon results as indicative only of certain complex vital conditions which should be ascertained, and, as far as possible, to regard the proximate causes in all our prescriptions (§ 673, 674, 699, 741). Here we have a patient with a cough. A favorable or a fatal issue of his case may depend entirely upon the exhibition of the right expectorant. He may be cured by tartarized antimony, or may be killed by squill, seneka, or bloodroot. It is evident, therefore, that "coughs" depend upon important varieties of pathological conditions; though, when the direct result of pulmonary disease those conditions are generally of an inflammatory nature. There may be numerous gradations of the form of common inflammation from that which constitutes pneumonia, and speedily runs its course, to that indolent state which persists for years, and makes little or no impression upon the general health.

All this, however, is doubtless obvious to enlightened practitioners; out, when it is considered what morbid anatomy is about, even with common inflammation (§ 699), and, how deplorable the evils which have sprung from the pathology of scrofula and tuberculous phthisis that has issued from the purlieus of Paris, I am moved by the conviction that I cannot attempt a more useful service to humanity than by exploring the subject now under consideration.

It has been no uncommon and fatal error to have exhibited stimu-

lating expectorants (which, indeed, commonly form the "cough mixtures"), in active forms of pneumonia, under the belief that these stimulating agents possess the power of at all times producing expectoration, and that this result is the main object to be contemplated. Sometimes, however, these agents produce vomiting, and their effects are then less disastrous; or, in subdued forms of acute inflammation this sedative influence may barely counteract the stimulant virtue, or it may be useful. It is like employing snuff for nasal catarrh (§ 228 a).

892\frac{4}{5}, f. Coming to special modifications of inflammation, the expectorants in common use perform their morbific work according to the variety of the disease, and the part of the pulmonary mucous tissue,

or other tissue of the lungs, in which it may hold its seat.

Readily as that modification which constitutes croup may be removed in its early stages, a pernicious custom exists of prescribing stimulating expectorants. It is true, they are often united with tartarized antimony in the treatment of this disease; and a formula of this kind exists in the United States Pharmacopæia, bearing the name of the Compound Honey of Squill. That may be well enough, unaccompanied with directions for its use, with the exception of the honey, which is of no use whatever, never fails to injure the stomach, and often produces colic in healthy people. But, the compound is there, however, with the obvious design of supplying a convenient resource to the practitioner in cases of "cough," and especially that which attends the croup. In Wood and Bache's Dispensatory, of which the United States Pharmacopæia forms an important basis, it is said by the editors, that it "requires an explanatory commentary, in order that its precepts may be fully appreciated, and advantageously put into practice." Now, after stating that formula, the editors remark, that "this is the preparation commonly known by the name of Coxe's Hive Syrup." Indeed, such is the translation of the original Thus:

"MEL SCILLÆ COMPOSITUM. U. S. Compound Syrup of Squill.

Hive Syrup."

In this are four ounces, each, of squill and seneka, and two pounds of clarified honey, along with four pints of water and forty-eight grains of tartarized antimony, boiled down to three pints, or about three

pounds.

Such, then, is a standing formula for croup, with the very name of the disease associated with it; and a more dangerous weapon was never put into the hands of the profession. Compared with the lancet, which is so often represented in a similar manner, the ratio is about the same as computed by Smith between the "hero and the murderer" (§ 569, e). In all the cases, however, the questions at issue are to be decided by the force of facts.—Notes F p. 1114, Mm p. 1141.

If the mischief attendant on the "Hive Syrup" were limited to croup alone, these remarks, perhaps, had never been written. But, "cough" upon "cough," reaching even to all the stages of pulmonary phthisis, make their frequent demands upon "Hive Syrup." The antimony which it embraces atones but little for the offenses of its associates in most of the cases where they are called into action.

892\frac{4}{5}, g. It is resolution, not expectoration, which is wanted, when it can be obtained, in all the cases of active inflammation,—ay, in all of pulmonary phthisis before suppuration supervenes (\xi 700 b. 705,

732 d, 862-864, 890 e). If the disease be of such intensity that resolution may not be effected by tartarized antimony or ipecacuanha, no time should be lost in calling upon general or local bloodletting, cathartics, blisters, &c. And when we consider how these accomplish the intention to which the expectorants are inadequate only from the force of disease, it will go with the many other analogous considerations disseminated in this work toward clearing up the philosophy which interprets the operation of expectorants, whether in their curative or morbific relations to disease. Or, again, if bloodletting fail of arresting pneumonia, for example, we may pursue the philosophy in another aspect; since, while it has relieved the violence of the malady, it has brought on expectoration. It has so modified the inflammatory condition that mucus is generated in preternatural quantities; and therefore we see that bloodletting itself may operate as an expec-We now exhibit tartarized antimony, and it may either increase or diminish the expectoration; and, in doing either, it contributes to the decline of the disease. The expectoration, therefore, is a mere result, a mere symptom, of a certain change in the action of the organs by which the mucus is secreted; and it may be the result of a favorable or an unfavorable change. It appears, therefore, that whether the agent will or will not increase the mucous product, or, on the other hand, diminish it, depends upon the exact influence it may exert upon the pathological condition. All this clearly brings the operation of the several agents upon a par, and admonishes us to study their virtues, their mode of operating, and the precise conditions of disease to which one or the other may be applicable ($\{694\frac{3}{4},741\ b\}$).

But, let us pursue yet farther the case of pneumonia. Let us suppose a slow termination of disease. Antimonials finally cease to bestow any farther benefit, and the cough has subsided into one of a low chronic nature, without much expectoration. Here it is, if there be no strong tendency to scrofula, that squill, seneka, and other stimulating expectorants, may become highly useful; and if the cough be frequent and short, denoting an irritable state of the lungs, we associate an opiate, which not only allays the cough and moderates the stimulant effect of the expectorants, but increases the expectoration; and thus the opiate becomes an expectorant, though neither this nor bloodletting are ranked in that group of remedies (§ 872 a, 891 i).

A blister is also applied to the affected chest, and now, again, expectoration either increases or declines; though, in either case, there is a manifest abatement of disease as a consequence of the counterirritation ($\sqrt[6]{111-117}$, $233\frac{4}{5}$, $647\frac{1}{2}$, $891\frac{1}{2}$ k, 893 a, c, e, 905 a, 227).

But, perhaps the cough has ultimately become complicated with disordered digestion, or, it may be chiefly maintained by some gastric derangement. It is dry, and the usual expectorants render it still more irritating and husky. The remedy, therefore, is wrong, and has not been addressed to the essential pathological condition; which consists of some derangement of the stomach, while that of the lungs has become mostly sympathetic. Whatever will now relieve the former affection may remove the pulmonic. For this purpose tonics may be useful, and, as relief follows in the lungs, expectoration may be one of the results (§ 905). Tonics, therefore, in cases of this nature, become expectorants, and equally so as any of the agents which are confined to this denomination of remedies. It is obvious, too, that

they all operate upon common principles when they promote expectoration; and whether the result will follow one or the other, will depend upon the existing state of the system, in a general sense, and more particularly upon the precise pathological condition of the lungs. It is apparent, therefore, that remedies from almost any group may be expectorant; bloodletting, cathartics, emetics, narcotics, tonics, counter-irritants, and even alcohol. The last, indeed, in the form of hot toddy, is a popular remedy for colds. It may or may not increase expectoration. It may relieve, but more generally aggravates the

disease (§ 756). Will Chemistry explain (§ 892 b, 892 $\frac{1}{2}v$)?

Old neglected coughs from ordinary catarrh, and what is known as the old man's cough, come under that condition of common inflammation to which the stimulating expectorants are adapted. But, however protracted may be the specific varieties, as in hooping-cough, and pulmonary phthisis, they cannot be employed without endangering life. Their effect, indeed, in hooping-cough is so obviously bad that they are not often employed in its treatment; but, in pulmonary phthisis, and especially in the catarrhal affections of scrofulous constitutions, we every day witness the penalties which are paid for substituting morbid anatomy for the vital signs of disease, and in defiance of the plainest demonstrations which therapeutical agents can supply

(§ 137, c, 662 a).—Note F p. 1114.

8924, h. The sympathies to which the lungs are liable from many diseases of other parts, especially of the digestive organs, and the more or less reciprocal effects of their own diseases, by which endless reflex nervous actions may be set in operation, together with the situation of the lungs in a bony cavity, frequently render it difficult to ascertain their exact pathological conditions, and to distinguish what may appertain to pulmonary disease from what may be due to the play of sympathies. The stethescope, like the long-established method of percussion, has contributed much to clearing away the obscurities, and has done its good part in substituting pathological considerations for mere effects, and has shown us that cough, difficulty of breathing, &c., are not diseases, but merely symptoms of disease. The scientific physician, therefore, no longer administers expectorants, &c., for the relief of cough, or dyspnæa, but he applies the various agents to overcome pneumonia, pleuritis, bronchitis, laryngitis, pharyngitis, &c. In one case there is something tangible, intelligible, and susceptible of certain and speedy relief; in the other, or where the prescription is made to the symptom alone, all is confusion, uncertainty, and death. Or, it may be some organic affection of the heart, or gastritis, or enteritis, or little more than moderate degrees of indigestion, upon which the cough or dyspnæa depends and yet where, from want of a proper anatomical knowledge, or of physiological and pathological science. the most unhappy mistakes are made with the expectorants, but where the better informed are often greatly aided, in their embarrassments. by the stethescope.

But great as is the acquisition of the stethescope, the reign of morbid anatomy has surrounded it with many abuses; the vital signs are either neglected or held to be of very subordinate importance, and the instrument is turned in pursuit of structural lesions. If cough and dyspnæa supervene upon abdominal derangements, the source of the symptoms is not seldom found in some special lesion of the heart, or, others detect in the supposed cardiac lesions the cause of an intermittent or irregular pulse that depends on hepatic disorder (§ 390 b, 688 k, 806, 811). These mistakes are a fruitful source of malpratice, and are common among the disciples of morbid anatomy (§ 697, 699 c, 701).

892\frac{4}{5}, i. The foregoing considerations appear to be indispensable to all who would enter understandingly upon the treatment of pulmonary affections, or to distinguish what is relative to the lungs from what is due to other organs, or to comprehend the modus operandi of the remedial agents, whether they be employed under the denomination of antiphlogistics, vesicants, pectorals, expectorants, &c., or their philo-

sophical and comprehensive name of alteratives.

To the young practitioner, at least, I would say that it should never be forgotten that every inflammatory state of the mucous tissue of the lungs, however mild or chronic, is liable to become exasperated, and to give rise to pneumonia, or to croup, or what is extremely common, to phthisis pulmonalis. And when we again consider how often the last affection has been developed by the stimulating expectorants, I think that I do not err in my estimate of their relative uses and destructive effects in saying that mankind would be benefited by excluding from the treatment of pulmonary diseases all the reputed members of that group of remedies excepting those which belong to the first of the foregoing subdivision (§ 8924, c). Independently of the direct practical results, attention would be turned upon bloodletting, antimonials, &c., and their strikingly salutary effects in numerous cases of common inflammation of the pulmonary mucous tissue, and in the early stages, especially, of those inflammatory states which lead to pulmonary phthisis, would revolutionize the whole system of morbid anatomy, and eradicate the pathology which has been founded upon it. The laws of the nervous system should banish the "speciality".

In the next edition of my Materia Medica (and I make the suggestion on account of its practical bearing), it is my intention to substitute for the term Expectorants another which shall refer to their modus operandi; probably, Alteratives adapted to Pulmonic Inflammations, and I will rank bloodletting as the first, in a general sense.* This will take in, also, tartarized antimony, and ipecacuanha, in emetic doses. Its advantages may be variously illustrated. Almost any condition, for example, of muco-pulmonic inflammation may be accompanied with a strong predisposition to inflammation of the pleura, or, they may occur together, or in the form of pleuro-pneumonia. Very many turn directly to the expectorants, and, if they find their attention arrested at once, under an equivalent denomination, by bloodletting, and tartarized antimony, and unfettered by the term expectorants, the appropriate remedies may have a good chance of raising inquiry, and their trial may awaken new views in pathology, and dissipate some of the prejudices against loss of blood. The practitioner will soon imbibe the conviction which experiment produced in the distinguished Cleghorn, that bloodletting can scarcely be misapplied under any conditions of pneumonia, and be led to avoid the stimulating expectorants, as he will all the tonics, when he approaches the treatment of most inflammatory affections (§ 1005, h). In proportion as the loss of blood is less likely to be useful where any form of pulmonic inflammation, to which this remedy may be adapted, shall refuse to yield to its power, so in a greater ratio will the non-stimulating ex-

^{*} This improvement was made in the edition of 1848.

pectorants, and all other means, be likely to fail. How unavailing therefore, must be those stimulating expectorants which are so often prescribed, even by those who confide in early bloodletting, at the advanced stages of pneumonia! The sole object in view is that of increasing or starting expectoration, without any reference to the morbific virtues of the supposed remedy. Let us, therefore, have the best remedy, however late, whatever the sex, whatever the constitution or the age; and that remedy, in the cases supposed, will be the loss of blood, as affording the best chance for life. Whenever acute forms of inflammation subside into a chronic state, neither the pathology nor the principles of treatment change, unless as it respects partial modifications. In a general sense, the direct antiphlogistic plan should be continued (§ 752, &c., 1007 b, c, d, 1008).

In the language of the celebrated Dr. Freind, "There are some, perhaps, who may think these various inquiries into disease may not be of much service to the healing art. However, they must allow me to affirm, that it is of very great importance to physic that we have an accurate knowledge both of the peculiar signs and of the nature of each distemper, and, also, of its seat; for these being found, we shall be much happier in our inquiries into the means of cure. Whoever, therefore, perfectly understands the nature of a pleurisy, or peripneumony, will easily perceive what immediate relief may be had from opening a vein; for, upon this point so depends the whole safety of the patients, that, if you should depart from this kind of medi-

cine in vain will you seek for any other."

But, I would finally say of pneumonia, that however the disease may abate under the direct effect of loss of blood it not unfrequently happens that the symptoms recur with more or less violence. It is this which we are to anticipate and watch, and to repeat the remedy from time to time as returning symptoms may suggest, and before the disease can have recovered its original severity (§ 1005, h). In this manner, we shall constantly make advances upon it, and, with the aid of other remedies judiciously devised, we shall not often fail of success. These, however, are cases in which firmness, and a constant recourse to pathological considerations, are more or less in requisition. Sanguine hopes may be called up by the great relief which is yielded by the first outlet of blood, but, to be only in a few hours disappointed by the formidable signs of returning inflammation; and when, at last, we shall have met them again and again by our principal remedy, the disease may appear to have come to a stand, and scarce falters under the combined effect of general bloodletting, leeching, antimonials, &c. This is no time for discouragement, but rather to fear that our means, in coming short of the mark, have not been applied in sufficient vigor. Now is the time, I say, to push the high principles of our noble science, to throw off the trammels of prejudice, and let the blood flow, till, by the relief it brings, we win new trophies for ourselves, and for medicine (§ 1005 a, b, c, d, e, f, g, h, 1007 b, c, d, 1008, 1068 c).—See P.S., 1860, at p. 872. Also, Note F p. 1114.

COUNTER-IRRITANTS.

893, a. I enter now upon the consideration of those remedial agents which establish their influences upon internal organs through the medium of the skin; and here is opened to us a display of those sympa

thetic processes which take their origin in cerebro-spinal nerves along with the sensitive fibres of the sympathetic, and terminate in the motor fibres of the ganglionic system (§ 113, 224, 454 a, 461–461 $\frac{1}{2}$, 465, 473 c, 478, 488 $\frac{1}{2}$, 489, 512, 514 f–k, 516 d, nos. 12, 13, 520, 891 $\frac{1}{2}$ g, k).

That vesicants and leeches operate in the foregoing manner was expressed by me in the London Medico-Chirurgical Review in 1834. See

p. 827, § 1056.—Also, Rights of Authors, p. 914.

Counter-Irritants exert their effects upon parts remote from the seat of their application in the same manner as when cold applied to the surface excites the renal function, or lights up pneumonia, and through the very complex mechanism set forth at the beginning of this section, and in other places. Here, too, in the case of counter-irritants, we meet with an embarrassing diversity of central parts which govern the reflex nervous actions, and perplexing results as the irritant may operate through one centre or another—sometimes taking the route of the brain and spinal cord, and then proving morbific, or at other times operating through the ganglia or plexuses of the sympathetic nerve, or some portion of the nerve itself, in the vicinity of the counter-irritant, and then only proving curative (§ $233\frac{3}{4}$, 455 a, 456 a, $461\frac{1}{2} a$, 473 c, 478 b, 483 c, 889 g). We shall see, too, in all these influences the clearest demonstration that the nervous power is modified in its nature by the impression transmitted by the agent to the nervous centres (§ 481, $891\frac{1}{2}q$, k), and that it operates either as a directly morbific cause or is curative of existing disease by substituting pathological conditions more favorable to the recuperative tendency of the organic properties (§ 854, 900, &c.). Exactly the same philosophy, therefore, is applicable to the modus operandi of counter-irritants that I have hitherto represented as characterizing all other agents. But such is the diversity in the details relative to the laws and phenomena of the nervous system, whether resulting from its direct or reflex action, whether excited by the will, by mental emotions, or by direct physical irritations of the nervous centres in the former case (§ 227-230, 245, 481), or by transmitted influences to those centres from remote parts in the latter case, or as certain cerebro-spinal nerves are limited to a subservience of voluntary motion and sensation, or as others co-operate with the sympathetic by contributing to the essential office of the latter in harmonizing the organic functions, variously affecting the organic products in vital constitution, and perpetually exciting or depressing the secretory and excretory processes, and seeing how the latter mechanism is the great medium, through its physiological characteristics, of the transmission of the disturbing effects of morbific causes, and the restorative of such as are remedial (§ 113, 500 g, and references above), and, withal, the isolation of intermediate nerves when the mind or physical causes operate upon individual parts, and yet all determined by precise, however complex, laws, we find ourselves in a labyrinth where no light is admitted from the surrounding effulgence of inorganic nature, and recognize the impracticability of expounding its problems in any other than a language as foreign from chemistry and physics as are the functions and laws and phenomena of living beings, and the necessity of a copious analysis of all its parts (§ 5\frac{1}{2} b, 59, 64, 165-169).* And this leads me to recur to what I have said of the terms motor, sensitive, and reflex action in § 475, that I may now add that reflex action should be regarded as expressing simply a general result without implying in

^{*} Sea Notes AA p. 1131, Dp p. 1132.

the least the philosophy of the process. It may be made to stand for any hypotheses expressive of reaction, though least of all for that of galvanism, or any other emanating from the science of chemistry. The reflection even of polarized light, with all its modifications, would not serve as an analogical basis for the reflection of any influences transmitted to the nervous centres or of the nervous power, and all analogy disappears in those influences which take their rise in the centres themselves, or such as I have designated as direct developments of the nervous influence, and which, from the absence of centripetal impressions, and from engaging only the centrifugal nerves, discloses the defective import of the term reflex action. Nor will I neglect this opportunity of adding to § 409 k the important fact that the hypothesis of galvanism, as applied to reflex action of the nervous system, violates the indispensable requisite of a continuous circle, and contents itself with the most irregular segments, and these segments and curved lines consisting of two parts differently endowed, and manifesting peculiarities of function that bear no analogy to galvanism. Nay more; for in a still more discreditable manner it professes to be the agent concerned when the nervous influence, as in mechanical irritation of the nervous centres, engages only the centrifugal nerves, and then operates in a straight line! The experiments upon the frogs prove nothing beyond the fact, for here a continuous circuit is formed and galvanism developed. are nothing more than the rudest experiments with inorganic matter.*

893 b. In my Materia Medica and Therapeutics I have arranged Counter-Irritants, with numerous other remedies, as an Order of Antiphlogistics, and under the general denomination of Cutaneous and other Local Applications. The counter-irritants consist of Vesicants, Rubefacients, Supparants, Escharotics, Potential Cauterants, and Actual Cauterants.

893 c. Vesicants are by far the most important, though mostly confined to the blistering insects. The two next groups operate essentially after the manner of vesicants; but escharotics and cauterants are generally limited to simply local effects, and with only that obscure instrumentality of the nerves which must arise from their incorporation in compound tissues (§ 746 c), though often giving rise to local reflex actions, especially moxas, but too moderate for much effect upon internal parts. It is otherwise, however, with vesicants, rubefacients, and suppurants, which not only exert their useful effects through local nervous centres, but in unsuitable states (§ 893 n, p) the first two often send their influences to the cerebro-spinal axis, and thus develop a general reflex action that disturbs especially the motions of the heart and arteries, which are far more readily affected by these causes than the functions of any other organ (§ 113-117, 224, $226-233\frac{3}{4}$, 339, 409 k, 446 a, $454-461\frac{1}{2}$, 478, 480-485, 489, 490, 500 dd, k, m, 512, 516 d, no. 3, 524 d, no. 7, 526 a, b, $687\frac{1}{2}$ - 688, 714 - 719, 746 c, 826 cc, 829, 846, $891\frac{1}{2}$ g, k, 892 b, $892\frac{1}{2}$ v, $893\frac{1}{2}$, 902, 904 c–905, $905\frac{3}{4}$, 952, 961 a, 1059). Again, also, when vesicants lead to irritative inflammation, which is often the case with children, and in the sanguine and nervous temperaments, or in others where general irritability is morbidly increased, the nervous power may be brought into general operation, and we may witness the full display of reflex nervous actions in one almost universal commotion of the body (§ 150). This may also follow too extensive an application of a blister, or of rubefacients, though no excessive irritation be produced in the skin; just as a scald of limited extent may be * See Note Y p. 1130

salutary, while another less intense, but spreading over a greater surface, will be often fatal. In all these cases, however, the effect is morbific, and they exemplify the very close analogy between the operation of morbific and remedial agents (§ 901). It is, indeed, the amount of the agent, whether physical or mental, and the existing state of the body, which makes all the difference between salutary and morbid results. The amount of a remedy, which had been curative in one case, may, in the same dose in another case nearly analogous, or if not exactly applied, lead to a fatal issue. In the case of vesicants, their action should be so circumscribed as to operate mostly through local nervous centres, or by contiguous, not by remote sympathy; and hence a use of these terms (§ 497, 638½). Bloodletting will secure this by lessening irritability and general reflex nervous action (§ 224, 1038).

In the preceding discussions upon the materia medica I have been extensively employed in seeking out the provisions which the Author of Nature has so bountifully, however intricately, ordained for the relief of those principal diseases of mankind, fever and inflammation. And yet we have often had occasion to see that many of the most valuable agents for these purposes are directly productive of inflammation when unskillfully applied. This is often exemplified by many of the cathartics; and the Peruvian bark, and its analogous tonic associates, will relatively cure or exasperate intermittent fever according to the exact conditions under which they are administered. We have seen, indeed, that even wine, brandy, &c., now and then become remedies for fever, and even for inflammation (§ 752, &c., 892 g, p). The apparent contradictions I have endeavored to reconcile, and to show that the occasional coincidence in the results of agents which are opposed to each other under ordinary circumstances is due to a common law which governs the operation of all causes upon organic life. The causes operate upon those properties in which life fundamentally consists, and thus give rise to healthy, or morbid, or curative effects, just as they happen to affect those properties (§ 137 d, 150, 151, 177, 189 b, $350\frac{1}{2}$, $350\frac{3}{4}$, 569 a, 638, 852 a). In disease, as we have seen, their susceptibility is variously altered from the natural standard, and variously so in any given disease, as in fevers and inflammations; according to the numerous fundamental and transient circumstances already set forth. It may be, therefore, that, in a few cases of common inflammation bark or wine will place the diseased conditions in as favorable a state for the recuperative efforts of Nature, as bloodletting and cathartics will do it in most other instances; and when either produce this auspicious change they are antiphlogistics. It is upon this principle, therefore (or that of the general tendency of a vast range of therapeutical agents to establish salutary changes in febrile and inflammatory disease, when duly employed), that I have assemvled the most useful part of the Materia Medica under the general denomination of Antiphlogistics.—See Note Ee p. 1133.

The foregoing remarks are preliminary to a farther exposition of the same principles which are concerned in the therapeutical operation of the group of agents upon which we have now entered, and which are curative by exciting inflammation, or analogous conditions; and the best of them are such as will effect, in a given time, the nearest approach to a full development in the skin of the most simple form of common inflammation (§ 721, 722, 729 a). These means are, prin-

cipally, cantharides, issues, and setons. Their immediate action is strictly morbific; and they have no salutary effect upon existing inflammations till they produce a corresponding disease, or, at least, that morbid irritation which forms the access of inflammation, in some part of the surface of the body. Then it is that this artificial inflammation or irritation so modifies the natural one, that the latter may subside, rapidly, without any other curative influence; while the artificial one is so peculiarly constituted by the nature of the remote cause, that that, too, readily takes on a disposition to subside, and thus the patient escapes from the inflictions both of Nature and of art (§ 133 c, 137 e, 150, 151, 639 a, 852, 853, 854 c, d, e, 858, 905 a).

893, d. It has appeared to me a matter of no little importance to consider the foregoing facts and the philosophy which concerns them; since, in connection with what has hitherto been said of the operation of internal agents, and connected with what is yet in prospect relative to the special influences of loss of blood, they open widely a view of the great principles of solidism and vitalism, and of the stupendous laws by which healthy and morbid processes are carried on, and illustrate that connecting medium between them which is constituted by the various gradations of the restorative movements as instituted by remedial agents under the great recuperative law of organic beings. The whole is but an intimate chain of analogies from the most perfectly healthy state to the gravest conditions of disease (§ 901).

We see, also, distinctly exemplified by the mode in which blisters, setons, &c., produce their favorable results, that absolute remedies institute the process of cure in virtue of their morbific qualities; and this becomes the more striking when we associate with the alterative influences of vesicants upon internal inflammations, through the artificial disease which is established in the skin, those natural cutaneous inflammations, as erysipelas, &c., that are subdued by the direct contact of the vesicant with the inflamed surface (§ 893 1, 1059).

893, e. We may now pause, for a moment, to observe how clearly the various effects of cantharides prove the operation of curative agents, either by a direct action upon the organic properties of a diseased part to which they may be applied, or through the instrumentality of the nervous power when they extend their therapeutical sway to distant organs, and how, also, the nervous power is variously modified, and variously reflected upon remote parts, according to the nature of its exciting causes (§ 227, 228, 230, 2333, 497, 500). The common mode in which cantharides, setons, moxa, scalding water, burns, &c., relieve or increase deep-seated inflammations, or disturb the system at large, is clearly manifest; and since only one of the foregoing agents is liable to absorption, every precept in philosophy divests the coincident effects of cantharides of a shadow of possibility that they are due to an absorption of the agent. We have seen, too, how erysipelas may be removed by the direct action of cantharides upon the part inflamed; and this (especially when associated with the remote effects of all other remedial agents) assures us, as a next link in the demonstration, that a modification is imparted to the nervous power, according to the special virtue of the remote cause, which operates, in that particular instance, upon the remote part in a mode corresponding more or less with that which is observed in the primary action. And now if we look at what is often going forward in the bladder, we shall see yet farther (something for the senses, something for "experimental philosophy") that the nervous power actually acquires the virtue of an inflammatory agent, and analogous, too, to the specific characteristic of that virtue as it appertains to cantharides. Now carry this to those inflammations which are constantly springing up in different parts as consequences of each other, in the natural round of disease, and you will come with me to the conclusion that the same philosophy obtains throughout. It is exclusive of absorption in the case of the bladder, besides other obvious objections.

It appears, therefore, that when erysipelas yields to the direct action of vesicants it is by the substitution of the kind of inflammation which cantharides produces in the sound skin, and which subsides spontaneously and speedily. Again, other local applications, as nitrate of silver, iodine, mercurial ointments, &c., will effect the same result by introducing other and very different pathological changes, or the erysipelatous inflammation may be subdued by loss of blood, or by cathartics, or by the constitutional action of mercury, or perhaps by stimulants. It is manifest, therefore, from all this variety of means, leading to a common result, that the cure depends in all the cases upon the substitution of some artificial pathological condition which is capable of spontaneous subsidence, though the changes which are thus forcibly introduced are as various as the remedies (§ 854, 892 b, c, 897–902, 904 d, 905, 1059).

But, though the cantharides supply an apt illustration of the whole philosophy of our subject, and, like the natural developments of inflammation which follow each other by reflected nervous actions, denote a modification of the nervous power in great conformity with the nature of the causes by which it is brought into operation, there is, nevertheless, a great variety of remedial agents, which, in their therapeutical doses, manifest no action upon the organ to which they are applied, and through which they overcome disease in parts remotely situated; as also other important ones, like mercury, when applied to the skin. And, although it be rendered obvious by the morbific effects of these agents that they modify the nervous power in their therapeutical aspects as much according to the nature of the several agents, respectively, as do cantharides, issues, setons, or as when one natural inflammation supervenes upon another, I have made the qualification which is due to a subject hitherto so entirely unexplained, that the modifications of the nervous power take place under the influence of its own nature (§ 228, a, $892\frac{1}{2}$ c, 896-901, 1059, 1088 b, c).

Finally, in respect to the modus operandi of cantharides, when considered in its analogies to other vesicants, issues, &c., we have an interesting view of the specific relations which the special virtues of certain remedial agents sustain toward the modified irritability of particular parts of the organism, and a proof, also, of the diversified conditions of irritability in different parts, and of the remarkable manner in which the nervous power is reflected with salutary or morbific effect through certain motor nerves by the peculiarities of each exciting and modifying cause (§ 233\frac{3}{4}, 500 g), while there is simultaneously presented by the operation of cantharides a curative influence upon all parts that are affected by disease, and a morbific one upon a special part that was antecedently in its natural state (§ 150, 151, 188 a, 190 a); but its action is useful only through local nervous centres.

893, f. From what has been now said, it is manifest that vesicants,

issues, setons, and other counter-irritants do not produce their favorable effects through the discharges to which they give rise; though this is one of the principal interpretations in the humoral pathology. The effusion instituted by cantharides is so unimportant that it can scarcely be taken into the account in explaining the curative influences of this agent (§ 863). Moreover, it frequently happens that blisters afford all the relief of which they are capable by acting merely as rubefacients. This, indeed, is oftener true than is commonly supposed, since vesicants are generally permitted to remain till vesication is established; though in numerous cases this extent of their action is un-

necessary (§ 497, 1038).

Since, therefore, cantharides will often answer its intention when employed only as a rubefacient, and operates at all times through the vital impressions it exerts upon the skin, it may appear unimportant to some whether this or another agent be employed for the purpose of counter-irritation. Such, indeed, is, unfortunately, supposed to be true by many practitioners, who resort to mustard cataplasms, or ammonia, &c., where cantharides would be a far more useful agent. So true is this where active inflammation affects any of the important viscera, and vesication has become appropriate, and may be of the highest importance, the rubefacients, which operate speedily, have little or no salutary effect, and are often detrimental by increasing

constitutional irritation (§ 150, 151).

893, g. The foregoing remarkable difference in results (f) is owing, in part, to the difference in the virtues of the remedies, and, in part, to the difference in time occupied by the several agents respectively. In all cases of very rapid irritation of the surface, vesication, &c., whether induced by ammoniated lotions, mustard, boiling water, moxa, &c., the curative effect upon deep-seated inflammations is far less than where the artificial disease is more slowly instituted. It is, nevertheless, of no little moment, in the case of vesicants applied for active forms of disease, that the irritation of the skin should advance with considerable rapidity, and that vesication should ensue, at adult age, in from six to twelve hours. That is the most useful period; and when the full action of cantharides is longer delayed, whether by some defect in the remedy, or by a subdued irritability of the skin, the curative effect is commonly less obvious.—See p. 298, § $476\frac{1}{2}h$.

It is also proper to observe, in a philosophical as well as practical sense, that time has various influences, according to the modification of disease, its seat, its duration, the constitution, sex, age of the subject, &c. It relates to the nervous power, and is explained in § 479.

But, in no respect is the influence of time so remarkable as seen in the difference of results in the treatment of acute and chronic diseases; in which respect counter-irritation is on a par with other remedial influences. When inflammation is recent, the usual rapidity with which cantharides operates is best suited to almost all forms of the disease; but when it has run into a chronic state, and has become the subject of habit, it frequently happens that tardy suppurants, such as setons, issues, tartar emetic ointment, &c., are highly useful (§ 535, &c.). Yet there is no doubt that the difference in results as it respects the time of these cutaneous agents, in the acute and chronic forms of inflammation, has been often much overrated; especially the advantage of a suppurating surface in chronic diseases. It is apt to be supposed, in

these cases, that there is something to be discharged, either "concoct-

ed matter," or such as refuses to be concocted.

893, h. Although it be true that chronic inflammations oppose to counter-irritants the obstinacy of morbid habit, and naturally suggest the long-continued and uninterrupted influence of issues, &c., experience has fully shown, that, in most cases of low indolent inflammations they are surpassed by a frequent succession of blisters. This experience, too, has mostly banished from use the savine ointment, and other agents, which were but lately and largely employed to maintain the action instituted by cantharides. The difference goes, with an endless variety of analogous facts, in illustrating some of the profound problems of organic life. The uninterrupted action of issues, the prolonged ulceration of vesicated surfaces, &c., are more or less apt to establish a morbid habit peculiar to the modifying agents; and, although it be a first step in the series of changes which are necessary to establish the full recuperative process, the pace is retarded by the habit induced. To break this force of habit, it is only necessary to intermit the agent during the time required by the healing of a blister. The curative impression remains, and the irritability of the organ diseased undergoes an increased susceptibility to the agent at its successive renewals. Each repetition gains upon the last, and often presents the aspect of cumulative influence. The principle is shown in relation to many things, and may be seen in the action of antimony, opium, &c., in former sections (§ 550-556, 558 b, 889 m, 902 i).

The influence of habit of which I have now spoken, as it respects the artificial change induced in chronic inflammations by the uninterrupted operation of issues, &c., grows out of the analogous habit which the agent establishes in the artificial or curative disease, which soon lapses into that chronic state which is less and less sensibly felt by parts morbidly affected; while those parts, and the entire system, are gradually accommodating themselves to the artificial irritation, and by which this irritation loses still farther its sympathetic and curative influences upon the morbid conditions for which it is instituted. But if, on the contrary, a succession of irritations be employed, the habit of which I have spoken is neither established in respect to the system, nor the parts diseased, nor in respect to the artificial condition; but every successive repetition of the irritation produces nearly as profound an impression as the first (§ 150, 151). Here, too, along with the coincident effects of numerous internal agents, we may call up the advantages of repeated leeching, as presented in a subsequent section (§ 926), and in which reflex nervous action is equally concerned.

The same great principles are involved in all the cases. An elegant philosophy obtains throughout; and, although founded upon the great Institutions of Organic Nature, it is surrounded by so many of the qualifying circumstances that are incident to the instability of the vital properties, it can be fully appreciated and converted to the high practical purposes of which it is susceptible only by a careful, impartial, and unremitting attention to the phenomena of organic beings.

893, i. The principles to which I have just adverted (§ 893, h) lie at the foundation of other practical facts connected with the success of counter-irritation. The impression upon the skin, for instance, must be carried to a certain intensity, and that will depend upon the nature and force of disease, and other obvious contingencies. If it be

slight, the necessary impression may not have been made; while, on the other hand, if in excess, then it may not only disturb the general functions of the body, but aggravate the inflammation which it is the design of the remedy to relieve. In this respect, therefore, there is a close analogy with the action of remedies, when administered inter-

nally, as it respects their doses.

Another important point to be observed is the extent of the surface over which an artificial irritation should be established. This will manifestly depend upon a variety of circumstances; upon the nature of the irritant, upon the extent, force, and situation of the disease, &c. If the usual agent, cantharides, be employed, and the surface irritated be of narrow limits, it may be insufficient to break in upon the morbid process, however intense may be the artificial irritation. On the other hand, however, if a very large surface be irritated, its reflex nervous action may be morbific, although the artificial irritation be not intense. The difference in effects is of the same nature as that which attends the small, deep burn of moxa and an extensive superficial scald; the former being of no importance, while the latter may be speedily fatal through a sudden and violent reflex nervous action.

But, there is a great difference between the effects of an extensive surface vesicated by cantharides, and by scalding water; and this probably arises mostly from the difference in the times which the remedies occupy. In the former case, the system is gradually accustomed to the reflex nervous actions, and may be but little disturbed, while, in the latter, the violence of the impression upon the system is proportioned to its instantaneousness; and the extent of the surface irritated being great, a violent shock ensues. In one case the remedy operates through local centres of the sympathetic nerve (§ 497, 893, a, c), in the other the cerebro-spinal axis is involved, and a general, sudden, prostrating nervous influence is developed (§ $476\frac{1}{2}h$,

479, 509, 893, c, p).

It is evident, therefore, that there is only a certain parallel between the effects of vesication by cantharides and scalding water, whether upon a small or an extensive surface,—scarcely exceeding the partial coincidence by which I have endeavored to illustrate the difference between small and large vesications by cantharides, and to expound again the principles concerned in the effects of agents which operate gradually or with great rapidity. The difference, indeed, is so great between the effects of vesication when the gradual result of cantharides, and those which are instantly induced by scalding water, that we may safely vesicate an extent of surface by the former agent which it might be fatal to attempt by the latter (§ 891, m). The tincture of cantharides, when applied to the skin, produces vesication with great rapidity, is far less curative, and oftener disturbs the constitution, than when vesication over the same extent of surface is produced by the common plaster.—See Experiments § 476½ h, 479.

Nevertheless, there are certain inflammations, especially of a neuralgic and rheumatic character, and not affecting important organs, in which a rapid and violent irritation of a very small surface, as by moxa, will sometimes overcome the disease. But these intense, sudden, and limited irritations, in affections of any of the important viscera, are

never useful (§ 479).

If the disease be of a different character from inflammation, as the suddenly painful affections of the stomach that are incident to indiges-

tion, or, as in colic, &c., the rapid irritation which is produced by the rubefacients may then afford immediate relief, and more effectually than might be yielded by the vesicating action of cantharides. These rubefacients are, also, often abundantly efficacious in the declining stages of articular rheumatism, or in low chronic states of that disease. But this is a peculiar modification of inflammation which will also yield, under the same circumstances, to some internal remedies which exert no salutary influence upon the common, or other modifications of inflammation (§ 661, 662, 756 a, b, 892 b, 892 $\frac{1}{2}$ v,904 d, 1059).

893, k. The vesicating plaster is generally made too small to yield all the benefit of which it is capable. Four inches square is a common size for the thorax and abdomen; while six or eight inches square are not only equally safe, but far more efficient, under the ordinary circumstances which justify or require this remedy. Indeed, so comparatively safe is it to institute an extensive irritation by means of cantharides, when the state of the system is properly prepared, and the force of disease is otherwise moderated, and so important is it in certain conditions of disease to effect a very powerful impression, especially in the cerebral inflammations that refuse to yield to copious abstractions of blood, that I have sometimes rescued patients by the apparently desperate practice of vesicating simultaneously the entire scalp and a large extent of surface upon the neck and shoulders. Where bloodletting has been thoroughly practiced, and inflammation remains obstinately seated in some great vital organ, a blister of twelve inches square may be necessary to determine a sufficiently powerful

nervous influence, of which six inches would fail (§ 479).

But, in respect to inflammation of the brain, it should be distinctly understood that vesication of the scalp is entirely inadmissible, unless the irritability, and therefore the susceptibility, arising from the morbid state, be greatly lessened by abstractions of blood, cathartics, The irritation of the scalp will be otherwise propagated with morbific effect upon the brain; which arises, in this instance, partly through continuous sympathy along the communicating vessels (§ 498). Nor is it expedient to incur the risk when immediate danger is not impending, but to apply the agent to the neck and shoulders. The same objection lies against the application of blisters to the immediate vicinity of the eyes and ligaments in their very irritable states of inflammation. But if, in these cases, the disease have lost its activity, or be of a chronic nature, the vesicant is then most efficient when applied near to the part affected. It sometimes happens, however, in chronic conditions, that the skin in the immediate vicinity becomes sympathetically affected through the same influences from the parts beneath as are propagated upon them, at other times, by vesicating the overlaying skin. These morbid states of the adjacent surface are generally obscurely marked; though sometimes abundantly apparent, as in active forms of articular rheumatism. The obscure conditions often become strongly pronounced by an irritative, erysipelatous inflammation which is set up by vesicants, and by leech-bites, and which commonly aggravate for the existing time the natural disease; though the morbific influence is apt to disappear, and leave the disease as it was, as soon as the artificial irritations subside.

893, l. It may be now said, as a general rule, that the liability of counter-irritants, when applied near to a part inflamed, to increase the

inflammation, is in proportion to the intensity of the disease, the intensity of the artificial irritation, and the rapidity with which it is produced. It may, therefore, be regarded as safe, in a general sense, to apply vesicants and rubefacients immediately over the affected parts in chronic inflammations. But this is far from being true of moxa,

where the affected part is in the vicinity of the surface.

And yet we have seen that it may be sometimes perfectly safe and useful to place an epispastic in direct contact with certain inflammatory states of the surface. This, however, is never true of common inflammation of the skin, and only so of a few specific varieties. Their successful treatment in this manner, as in the case of erysipelas, opens to us another illustration of the principles upon which remedial agents operate. The disease, being a specific modification of inflammation, has not the disposition to subside spontaneously which belongs to common inflammation. The remedial agent, therefore, varies the mode of inflammation, and thus introduces a modification in which the properties of life are brought into recuperative action. But, it is otherwise with common inflammation, since the virtues of cantharides are such as to aggravate this condition when brought into immediate contact with the part affected. The same explanation applies to the therapeutical effect of the spirits of turpentine when applied to a burn or a scalded surface; since, in these cases, the inflammatory state is turned from the common standard, and admits of the institution, by other irritants, of modifications more favorable to the recuperative process. And so of nitrate of silver (§ 893 d, 1059).

893, m. With the qualifications now made, it is obvious from what has been said of the modus operandi of counter-irritants, that they will be curative in proportion as they are applied to the vicinity of the seat of disease. Their salutary effects, like their morbific, depend more upon this approximation than upon any special sympathetic relations between certain parts of the surface and the particular internal organs; since it is mostly through local centres of reflex nervous action that these agents produce their curative effects (§ 497, 893 a, c, 905 a).

It is also a remarkable fact, that it appears to be of no great moment in what particular tissue of compound organs the disease is seated. Inflammations of either are alike affected by irritants as they are by loss of blood; but varying, in all the cases, according to the general

vital constitution of the several parts (§ 150, 151).

893, n. We have seen that it is the tendency of inflammation to limit itself to the tissue which it invades, and that its extension to other tissues of the same organ, or to other parts, is by remote or by contiguous sympathy (§ 497, 498). It is also particularly true of certain tissues that they are apt to extend the violence of their remote influences upon parts of similar organization; especially in specific forms of inflammation. Thus, rheumatic inflammation of the ligaments is very apt to invade the pericardium, and sometimes the dura mater; and, the peculiar inflammation which constitutes the mumps (cynanche parotidea) often involves the testes or the mammæ. There is much reason to think, in the former case, where the heart so often participates, that the inflammation is first propagated to the pericardium, and subsequently from that organ to the serous tissue of the heart (§ 141, 525-529). In the latter case, or that of the mumps, the affection of the parotid will frequently subside when the other glands become af-

fected; and the disease is then said to have undergone a metastasis,—a magnificent display of our alterative reflex nervous action. Articular rheumatism affords constant examples of this phenomenon, in its rapid and successive invasions of different joints, and the frequency with which it subsides in one as it springs up in another (§ 524 a, 3).

Now, there is a prevailing error in the pathological construction of this extension and subsidence of the disease, which has led to a very common error in practice. It is supposed that there is a translation of the disease from one part to another, an actual movement of the complaint -something, probably, after the manner of the gases, as represented in a former section ($\S 350\frac{1}{2}$, n). The phenomenon, in consequence, has long borne the significant name of metastasis; and if gout happen to go from the foot to the stomach, it wanders so much out of its way that it gets in the stomach the well-known and expressive name of misplaced gout. As all men, therefore, are greatly moved in their practical habits by theoretical views (§ 4), it is no less common to imagine that the rheumatic or gouty affection may be driven or invited back to its appropriate place. Hence the applications which are made to the primary seat of the affection, but from which disease has taken its departure. And so, also, counter-irritants are applied to the parotid gland, should the testes, or mammæ, become affected in mumps, in the expectation of calling back the disease which is so far astray.

In the first place, however, there is, in all these cases, nothing concerned but reflex actions of the nervous system, and nothing is wanted to render the treatment appropriate and intelligible but a knowledge of physiology and pathology. All the ambiguous results are directly referable to the laws which govern the operation of the nervous power, which now presents itself in the compound aspect of a mor bific and remedial agent among parts which have either strong natural relations, or which are especially susceptible of morbific influences that result in the condition which is the supposed subject of translation from one part to another; while, in its turn, the sympathetic disease propagates, after the manner of vesicants, curative impressions upon the primary seat of the disease by like reflex nervous actions.

Secondly, the artificial irritation excited with a view to recalling the disease (as in vesicating the joints when gout attacks the stomach, and this, too, even when that organ may be the primary and only seat of the affection) is very different from the modification of inflammation which constitutes the pathological state of the disease itself, and therefore would not become, by any reflected influence upon the parts beneath, a substitute for it; while it is certainly an anti-pathological mode of recalling the specific, or any form of inflammatory disease, in deep-seated parts, since counter-irritation is one of the principal means by which we remove inflammation of these parts.

The foregoing practice, as founded upon the doctrines of metastasis and revulsion, is contra-indicated not only by physiological laws, but by all experience. The practice has been wholly directed by hypothesis, and has not been sustained by any favorable results. We need go no farther in proof of this than the admitted failure of M. Louis, in his application of "blisters to the legs," to remove, upon the foregoing hypothesis, the gravest forms of inflammation and disorganization of the brain, intestine, liver, &c., which befell the victims of "The Typhoid Affection" at La Charité. And here we see again exemplified

in the extensive sway which may be exercised not only by the authority of a favorite writer, but in the pernicious tendency of conclusions in medicine that are founded upon the results of practice as directed by errors in principles, the proneness of man to rest his inquiries, his hopes, his reputation, the happiness and the lives of mankind, upon simple views of the most abstruse, stupendous, and comprehensive Institutions in Nature,—the Institutions of organic life (§ 4, $5\frac{1}{4}$, $5\frac{1}{2}$, $349\ d$, $350\frac{1}{4}$ – $350\frac{3}{4}$). But, let us have an example in relation to the effects of counter-irritation by cantharides, as propounded by the great head of the Necroscopic School. Thus:

"Blisters," says M. Louis, "ought to be banished from the treatment of the typhoid affection." "If they exercised any influence upon the duration of the disease in the patients who have recovered,

it was by prolonging it a little."

Again. "I have not only rejected vesication from the treatment of pneumonitis; I have also ceased to employ it in pleurisy and pericarditis." "How can we believe that the effect of a blister is to check an inflammation, when this blister is one inflammation superadded to another?"! "In thoracic inflammations, their usefulness is neither strictly demonstrated (according to the numerical method), nor even probable."

"One thing is most assuredly beyond question, and we should never be weary of repeating it: that the therapeutic value of blisters is not known; that it must be studied by the aid of numerous and carefully-

noted facts, just as if nothing at all were known about it."

If the reader be not conversant with the history of that kind of "experimental philosophy" upon which the foregoing conclusions are founded, or with the efforts which are in progress to give it an ascendency over the philosophy which Nature teaches, he may obtain some knowledge of their extent by referring to foregoing sections (§ $5\frac{1}{2}$ a, 349 d, 350 $\frac{3}{4}$ kk. Also, Med. and Physiolog. Comm., Essay on the Writings of M. Louis, vol. ii.).

Instead, therefore, of the unavailing efforts of applying blisters to the extremities for the relief of cerebral, or hepatic, or intestinal, inflammation, &c., let them be directed to the organs which are the seats of disease, by applying them over, or in the vicinity of, their regions, to obtain the advantage of local centers of reflex nervous action (§ 224).

As to the doctrines of metastasis and revulsion, which have had their origin in the phenomena of reflex nervous actions (especially as witnessed in the successive development and subsidence of disease as they obtain in gout, rheumatism, and mumps), the whole system is constantly supplying examples of the accession of one disease as the sympathetic consequence of another, and the subsequent decline of the primary affection as a sympathetic result of the secondary development. And here, by-the-way, we are presented, in the natural process, with a perfect exemplification of the principle upon which counter-irritants operate in subduing diseases remote from the seat of their application; and we may thus readily comprehend how it happens that the discharge from an ulcer, or a seton, or blister, &c., will be suddenly arrested, or the superficial parts turned into the worst conditions, by the occurrence of disease in some internal part (§ 740).

The foregoing play of sympathies, however, is far from being equally true of all organs, or of all forms of disease. It is most distinct-

ly pronounced where pulmonary phthisis is preceded by gastric derangement, when the occurrence of the former often takes the lead and relieves, for awhile, the latter affection; but only again to light up indigestion, and ulcerative inflammation in the intestinal mucous tissue (§ 803, 804). But, it is rare, perhaps never, that remote diseases are favorably impressed by any form of disease that may happen in the alimentary canal. On the contrary, indeed, all such conditions are likely to aggravate or to maintain any affections that may be re-

motely situated, their reflex nervous actions being morbific.

Nevertheless, such is the analogy between the reflex nervous actions of diseased parts,—between the rise and decline of diseases, in certain parts, as consequences of each other, and the curative effects of many internal agents, that a vast number of therapeutists, overlooking the relations of the alimentary canal to all other parts, confound these internal remedies with the external counter-irritants; classing them all under the name of revulsives or counter-irritants. And here is opened another wide door to an excessive abuse of violent internal agents, and where we may well contrast the ten-grain alterative dose of tartarized antimony, and the most powerfully-irritating cathartics, administered with a view of establishing counter-irritation in the stomach and intestine, with that prejudice against bloodletting which sees nothing of the counter-irritant in the effects of this remedy. And how well does not all this submission to theory admonish us of the importance of investigating the nature of the influences which are effected by loss of blood (§ 4)! We all know what is doing in the way of tartar emetic. But let us take an example of the same philosophy from among the cathartics; for this is the only way of helping the cause of humanity in such cases, or of arresting another evil (§ 878) upon a more selfish principle. Let us go to the erudite and ablest work on Materia Medica for an example; and we will have others respecting certain substitutes for bloodletting in a future section (§ 960). Thus, then, Pereira:

"Pliny truly observes that the juice of the elaterium apple is dangerous when applied to the eye; and Dr. Clutterbuck mentions that some of it 'getting accidentally into the eye in one instance, it occasioned severe pain and inflammation, with an erysipelatous swelling of the eyelids, that continued the following day.' We have a farther proof of its irritant properties in the inflammation and ulceration of the fingers of those employed in its preparation. When swallowed, therefore, elaterium irritates the gastro-intestinal membrane, and occasions vomiting and violent purging." "In some dropsical cases, I have known a single dose discharge several pints of fluid from the bowels. The gripings, and the increased number of evacuations, prove that the irritation is not confined to the mucous coat, but is extended to the muscular coat. Under the influence of a full dose, the pulse is excited, the tongue becomes dry, and sometimes furred, and great thirst is produced. Considered with respect to other cathartics, we find it pre-eminently distinguished by the violence of its purgative effect."—Pereira's Materia Medica.—Notes H K pp. 1117, 1119.

And yet is this cathartic commended above all other hydrogogues for the cure of dropsy; and even boldly so, upon the principle of its producing counter-irritation in the gastro-intestinal mucous tissue; that is to say, the same sort of inflammation which affects the fingers

when the juice is applied to the skin. It should be also said of so valuable a work as that from which the foregoing extract is made,—valuable as a system of *Materia Medica*,—that Pereira approves the practice, and of course, therefore, the principle. The principle is thus stated by the author:

"Its effects," he says, "in dropsy, are two-fold; first, absorption of the effused fluid; secondly, the stoppage of any farther effusion in consequence of the *metastasis* of vital action from the seat of the

dropsy to the intestinal membrane."

And again, he says, "In apoplectic affections, elaterium, as a drastic cathartic, sometimes proves serviceable on the principle of counter-ir-

ritation."—Note G p. 1116. Also, § 1065 d.

That is the doctrine. A metastasis of the inflammation to the intestinal canal; and such is the virtual effect. But I have shown that counter-irritants exert their good effects only through local centres of reflex nervous action, while they are injurious when they develop a general reflex action of any intensity through the brain and spinal cord, however those organs may otherwise participate; and such is the pernicious effect attending this counter-irritation of the intestinal canal.

Opposed to metastasis, revulsion, derivation, &c., is the doctrine of repulsion. Thus, in respect to the utility of vesicating the joints in acute forms of rheumatism and gout there is a strong array of opposite opinions. The objections to the practice are founded upon the same pathological conclusions that have led to the cultivation of ulcers, cutaneous eruptions, &c.; it being supposed that it is often the effect of counter-irritants to repel (as it is called) the disease from the joints, and to establish it upon the heart, the stomach, or other important organs. This supposed effect, therefore, is exactly the reverse of that which I have just considered, or the induction of disease to sound parts by counter-irritation. In one case, the advocates of metastasis suppose that they invite disease from one part to another not diseased; in the other they are employed in driving disease from the affected part to another part not affected.

That is the modus operandi. But, its fallacy is shown, at once, by the flitting character of gout and rheumatism; suddenly subsiding in particular joints and as suddenly invading others, or attacking the internal viscera, when counter-irritants are not employed. Indeed, it is now known that inflammation of the tissues about the heart is a very common attendant of articular rheumatism; and the fact that acute gout is, at present, rarely treated by vesication, yet as frequently as ever invades important organs, disproves the assumption as to the tendency of blisters to produce these results. But, I am not advocating the employment of counter-irritation in acute forms of rheumatism and gout; certainly not till the intensity of disease is greatly subdued by antiphlogistics of a sedative nature, and general reflex action reduced.

In connection with the last remark it is also worthy of observation, that free bloodletting in acute rheumatism is strongly opposed upon the ground of its tendency to involve the heart in rheumatic inflammation. But, in all the reputed cases the inflammation had probably already affected the heart before the abstraction of blood, and constituted cases for a very extensive application of the remedy. If loss of blood will surmount the disease more speedily in any other part than the united force of all other means, it cannot, surely, fail of a corresponding effect upon the main source of the circulation (§ 500 m).

893, o. Among the evil consequences of vesication is a bad condition of cutaneous inflammation, which either refuses to subside and annoys the patient by its excessive irritation, or it results in extensive ulceration, or in gangrene. These conditions are owing to a very morbid state of the skin, generally consequent on some formidable disease affecting the great viscera of the abdomen; especially the gas tro-intestinal mucous tissue (§ 689, l). They add, of course, greatly to the evils of the disease, and hasten a fatal termination, which is apt to ensue upon the disease itself. These effects of blisters are most frequently witnessed in scarlatina, and often along with parotis, and ulcerated, or sphacelating, fauces. But, happily, they are rather rare; certainly less frequent than is surmised by many. It is never possible to know the existence of the peculiar condition of the skin which gives rise to these consequences; no more so than we are able to infer the predisposition to erysipelas which is often established by abdominal affections (§ 689, l). From their rarity, also, an apprehension of their possible occurrence should never deter us from the use of blisters.

Strangury is another, and a frequent evil of cantharides, though it does not often aggravate any existing disease. The urinary bladder has no strong physiological relations beyond its own system of organs, and pain is not apt to prove morbific, of itself (§ 140, 422, 891 m). There is no way of preventing its occurrence in particular subjects

with any certainty.

893, p. The foregoing are the most obvious injuries which are produced by vesicants, especially by cantharides (§ 893, o). These unfavorable results, indeed, are commonly regarded as the principal ones to which the common epispastic is liable. But, there are others, which, though too often neglected, are far more important, since they are frequent, and often determine a fatal issue of disease. These evils arise from morbific influences which are propagated abroad either by too intense an irritation of the skin, or from creating the irritation under unfavorable circumstances (§ 893 c).

It is the last condition which is the most frequent cause of the unfavorable effects of blisters, and which, in the hands of superficial observers, have led to the denunciation of this important antiphlogistic.

The inauspicious states for vesication depend, especially, upon too exalted irritability of the parts diseased, or of other organs; particularly of the heart and general circulatory system. If blisters, or other counter-irritants, be applied to the skin in this state of morbid irritability, the diseased parts are roused to a greater intensity of morbid action, and the whole vascular system to a more violent movement; so that a series of untoward results is thus instituted, which sympathetically, and mutually, aggravate each other, and give rise to new morbid developments, till the multiplying reflex nervous actions may be arrested only by their own fatal tendency. Nor can I doubt that many of those terrible inflammations, and structural lesions of all organs, which abound in M. Louis' work on the Typhoid Affection, and which have been taken as the basis of the most important principles in pathology and therapeutics, were owing to the cause now under consideration; since this distinguished man was about as hostile to bloodletting as he became toward vesication, after witnessing the latter's ef. fects in the complicated malady which will be long celebrated in the annals of medicine (§ 893 a, c).

The system, in the advanced stages of fever, is generally in an irritable state, is oppressed with local congestions and inflammations; or whether so or not, the artificial irritant becomes a source of annoyance, and often adds to the dangers it was intended to avert. This, indeed, is especially the time when such useless local irritations should be avoided, or quieted if they exist. Remaining inflammations and congestions should be treated with as little additional disturbance to the system at large as may be possible in those advanced stages of fever which were the subjects of Louis' experiments, and of too many others. Or, if it be necessary to resort to counter-irritants for their removal, they should be, at least, applied in the vicinity of the affected organs, where, alone, they can be of any avail.

Independently, therefore, of the direct and immense advantages of bloodletting, cathartics, antimonials, &c., we realize more sensibly the force of their importance, in acute inflammations, at least, when we consider that without the antecedent aid of one or another, but of bloodletting especially, we are completely cut off from the benefits of counter-irritation. Nay, more; so great are the prejudices against the principal remedy for inflammation and fever, or so sparing is its application, that cathartics inflict many evils when they might otherwise be rendered highly salutary, or their necessity, as well as of epispastics, superseded by moderating general reflex nervous action.

In all grave inflammations loss of blood is indispensable to the most useful effects of cathartics, or to their safety, and is absolutely the only condition under which counter-irritation should be attempted. Just as long, also, as the disease may remain in force, or general or local abstractions of blood may continue to be useful, vesication should be delayed. This remedy may then succeed with the most happy effect upon any remaining disease, even though it have passed into some other form than that of inflammation.

In the chronic states of inflammation, whether of important or unimportant parts, a frequent renewal of blisters may effectually surmount many obstinate maladies. But here, again, these agents are often powerless, though not as mischievous as in acute inflammation, till decisive bloodletting have been adopted, and, not unfrequently, often repeated. This is every day witnessed in those advanced stages of indigestion where a low chronic gastritis is shown by tenderness over the region of the stomach, and where, too, the liver has generally become more or less involved in morbid action. Vesication will not reach this condition till general bloodletting or leeching shall have been duly premised; and cases are not uncommon, where, after repeated and large abstractions of blood, such is the force of morbid habit that the disease finally issues in copious hæmatemesis. There are, also, many of the fluctuating states of the stomach in chronic indigestion, where no inflammation has invaded this organ, in which blisters over the epigastric region, and without any other remedial agent, bestow great The appetite and digestion are at once improved, and the patient started along upon the road to health, and placed in a state for the full and rapid influence of change of air, exercise, &c. The analogy, too, in these cases, with the useful effects of tonics and stimulants in others, contributes farther light upon the therapeutical influences of the latter remedies (§ 890½). Again, among the sequelæ of fevers is constantly before us a variety of phases of indigestion in which vesication of the epigastric and hepatic regions brings great relief to the sufferer, when this remedy is properly sustained by a well-regulated diet, and other salubrious habits.

893, q. There are numerous remedies, besides those which have been under consideration, that operate more or less upon the principle of counter-irritation, and yet exert an alterative action peculiar to each. This is even true to a certain extent of leeching; the irritation of the bites, and even the new action which is instituted in the capillaries of the skin by the leeches, being analogous to the irritative process which is set up by the true counter-irritants (§ 498, 923).

But there are great modifications, in these respects, between the local influences of leeching, and the effects of the true counter-irritants, and, if we now turn our attention to the large group of agents under the denomination of local alteratives, as set forth in my Materia Medica, we shall see, that, in all the instances, each substance has an alterative action peculiar to itself; while, in many of the cases, as with iodine, the mercurial plaster, veratria, camphor, &c., there are associated influences analogous to those which form the great characteristic of the true counter-irritants. These, however, will of course depend upon the amount of absolute irritation which the several agents may produce in the skin; some, as gum ammoniae plaster, proving a very positive irritant, and affording relief to chronic inflammation of the joints more in virtue of this counter-irritation than of alterative properties peculiar to the agent (§ 227, 892 b, 900, 905 a, 1059).

That common principles, however modified in their general aspect, and however varied in the details relative to the several agents, respectively, are concerned in the principal results, is obvious from the fundamental simplicity of organic laws, and especially so from occasional coincidences in the curative effects of all the agents now under consideration. We see, for example, in cases of indolent tumors, chronic enlargements of the liver, spleen, &c., that almost any one of these local alteratives will sometimes yield complete relief. We see it following the application of either leeches, or blisters, or ammonia, or mercury, or iodine, or even of simple friction, &c.; and, if we next regard the corresponding effects of many internal remedies for the same conditions of disease, we shall not fail to detect a coincident and harmonious philosophy throughout (§ 892 b, 892½ v, 892¾ t, 904 c).

In connection with the foregoing subject, it may be useful to some who may be baffled in their attempts upon indolent tumors of low inflammatory growth to know the advantages that have often accrued to myself from the frequent application of a small number of leeches Where they may refuse to yield under this mode of treatment, vesicants, or iodine, &c., may ultimately prove efficient, when they might have been powerless without the antecedent influences of leeching. The tumors, indeed, may not apparently have yielded in the least to the virtues of the leech; but this remedy will have placed the diseased part in a state of susceptibility to the action of other agents. The principle has been variously before us (§ 556, c), and may receive another exemplification in the frequent necessity of general bloodletting and cathartics to the salutary effects of vesication, in the treatment of acute inflammation (§ $137 \ d$, 150, 151, $556 \ c$, $890\frac{1}{2} \ g$, $892\frac{1}{2} \ u$).

893, r. In all hemorrhages from important organs, we should regard vesication as a remedy next in importance to the general and local ab-

straction of blood, if the latter be also appropriate, as it commonly is in the early stage of the disease; and when, at more advanced periods, Nature takes on this recuperative effort, vesication is the principal remaining means by which we may contribute an aid that timely blood-letting would have greatly surpassed, and would have given to art what ultimately belongs to Nature (§ 805).—Notes F p. 1114, II p. 1139.

8937. Before entering upon the following SUMMARY REVIEW OF THE GENERAL PHILOSOPHY OF THE MODUS OPERANDI OF REMEDIAL AGENTS, whose operation I have resolved, essentially, by alterative influences of reflex actions of the nervous system, and with a reference, also, to what I have said so extensively of this universal agency in the organic life of animals, I will recall an important ground by which the reader may be aided in his conclusions upon this subject, and which had escaped observation till the publication of the Medical and Physiological Commentaries. Even Dr. Philip, in his experiments (§ 476-493), neglected the analogy of which I am about to speak, referred the modified secretions to chemical agencies, and sacrificed his great labors to the interests of chemical physiology and the humoral doctrines. This analogy is the admitted operation of reflex nervous influences in exciting muscular movements. But that is the only result that is witnessed. There is no obvious change in the muscular action from what is natural. Not so, however, with the results in the great processes of organic life. Here the secretions are not only increased or diminished, but modified in their nature, and various morbid conditions produced or removed; and hence it is assumed that these results must be owing to very different causes from that nervous power which simply produces contractions in the muscles. It is entirely neglected, in this rationale, that the vascular systems are totally different in their functions from those muscular fibres upon which the nervous power makes its obvious demonstrations, as in convulsions, vomiting, respiration, contractions of the iris, of the sphincters, etc.; and, although there is a vague apprehension with some that blushing is owing to nervous influences, yet as there is seen only a transient redness, even this ground of analogical reasoning to changes of vascular action that give rise to increased, or diminished, or otherwise modified secretions, or the production or removal of disease, etc., is equally regarded as an abstract fact that supplies no information upon the less obvious problems. Neither is it considered that the vascular apparatus manifests a far more exquisite susceptibility to the direct action of common stimuli than the muscular fibre, and therefore that the vessels may be equally sensitive to that nervous influence which so readily excites the fibre in muscular organs. Another difficulty consists in comprehending the modifying influences of the nervous power upon secreted products, and in its production and removal of diseases, etc., according to the nature of the remote causes; and this grows out of the habit of neglecting the phenomena and of reasoning alone from what is physically demonstrable. It should be also considered that the cerebrospinal system in subserving the structures of animal life exerts the effect only of a simple stimulus, while the ganglionic not only unceasingly modifies the natural organic functions and products, but, through this physiological constitution, to a far greater extent when morbific or remedial causes operate (§ 113, 224, 356 a, 422, 455, 461-461\frac{1}{2}, $475\frac{1}{2}$, 487 h, $488\frac{1}{2}$, 500 g, m, 524 d, no. 7, 526 d, $891\frac{1}{2} g$, k, 1059). See NOTE AA p. 1131.

SUMMARY REVIEW OF THE GENERAL PHILOSO-PHY OF THE MODUS OPERANDI OF REMEDIAL AGENTS.

"It seems to me that the explanation which represents Nature always pursuing a uniform course in her operations, drawing the same results from the same principles, has a greater degree of probability than that which shows her separating, as it were, this phenomenon from all the others, in the way which she produces it."—Віснат.

894, a. The philosophy which concerns the operation of morbific and remedial agents was a subject of consideration in the first two volumes of the *Medical and Physiological Commentaries*, and subsequently in an Essay which contributes to the third volume of that work. The question has also been investigated, extensively, in different parts of these Institutes. But, it is a part of the plan of the present work that its consummation shall consist of a distinct exposition of the important matter now before us, in the form of a summary review of the relative facts and doctrines contained in former sections.

894, b. In approaching, again, the modus operandi of remedial agents, I may first repeat the most essential points,—that the vital principle is a real substantive agent, of which the vital properties, irritability, mobility, &c., are elements, implanted in organic beings for the animation of their structure; that the nervous power was superadded also to the animal kingdom; that all organic functions are carried on, through their instruments of action, by the four vital properties which are common to all animated beings; that all vital agents, whether stimulant or sedative, whether natural, morbific, or remedial, operate directly upon these properties, as also the nervous power when concerned in developing motion or changes; that all disease consists in a modification of these properties and a consequent change of function, and is therefore only a variation of the natural states; that the vital property sensibility possesses a modification which I have denominated sympathetic sensibility; that the nervous power is a vital agent, and, like other agents, develops motion and induces changes by acting upon the organic property irritability, and is exclusively the exciting cause of motion in animal life; that this power or property of the vital principle in animals may be called, in a direct manner, into increased, or preternatural, operation by direct impressions, physical or mental, upon the nervous centres, or upon the trunks of nerves; that this power is the efficient agent of remote sympathy, is brought into operation by impressions made upon sympathetic sensibility, which are transmitted by this variety of sensibility, through sensitive nerves, to the nervous centres, and there develop the nervous power, which is reflected, through motor nerves, upon the irritability of such parts as may be determined by the various influences hitherto expounded, and thus become the exciting cause of motion, of morbific or therapeutical

changes, &c., in those parts upon which its impressions are made; that the nervous power is susceptible of modifications by the causes which bring it into universal operation, whether physical or mental, and thus partakes, under the influence of its own nature, of the special virtues of each exciting cause, to which principle is due its alterative effects according to the nature of the exciting causes; and, finally, that a common principle is at the foundation of the philosophy, whether the manifestations of the nervous power be displayed in subserving the natural processes, or in disturbing their normal condition and products, or in restoring disordered functions, or as the power may be concerned in developing motion, voluntary or involuntary, when propagated immediately from the nervous centres, and without, of course, the intervention of sensitive nerves, and therefore in a direct manner.

895. These several fundamental points have been critically presented in former sections (now too numerous for special reference), and they have all an immediate interest in the operation of remedies. They form the great principles which concern the natural operation of vital stimuli, and are, therefore, fundamental in the production and cure of disease. The plan of Nature is thus perfectly simple, consistent, and sublimely beautiful, in its foundation. The details are distinguished for their harmonious variety and intricacy, yet susceptible of the most complete analysis. We trace the complexities to the constitutional nature of the organic properties,—to their liability to multitudinous variations from their natural state, -to the various natural modifications which they sustain in different tissues and organs,—to the variety of those organs, and the differences in their respective functions,—to their intricate connections and dependences by means of sympathy,—and to the endless variety in the nature of the virtues of foreign agents which are capable of inducing modifications of the organic states of every part, and according to the nature of each agent.

Such are the great points to be kept in mind; but most of all, as it regards my present inquiry, are the various considerations relative to the nervous power, and its laws of reflex action, as hitherto set forth, and through which I interpret all the influences produced by morbific and remedial agents upon parts that are remote or but slightly distant from the direct seat of their operation, and often, in part, upon their direct seat of action, unless such influences are propagated by continuous sympathy ($\delta \ge b$, 143, c, 148-151, 495-529, 855, 895, 902 f).*

896. The whole philosophy of the operation of morbific and remedial agents rests, as we have seen, upon physiological principles. Exactly the same philosophy relates, also, to the corresponding effects of mental causes. The wound, or the poison, or the errhine, which convulses the muscles, the want of air which determines respiration, the impression of light which guides the motion of the irritation of fæces or of urine which maintains a contraction of the sphincters, the food which excites the muscular action of the stomach or the contraction of the pylorus, the cathartic which purges, the emetic which vomits, the narcotic which arrests diarrhæa, or allays irritability, or induces sleep, the gastric stimulant or the remote inflammation which rouses the sanguiferous system, or the sedative which prostrates the circulation, or as one or another may destroy life, produce their effects through a common law which is relative to the nervous power, and it is through that same law that the complex organization

^{*} Continuous sympathy is continuous influence of these Institutes (\$ 129 c, f, 498 a).

moves on in harmony in all its parts, that the mind brings into action the voluntary muscles, that syncope is removed by pungent vapors, or by a current of air, or by a dash of water, that cold to the surface determines the first inspiration of the new-born being, that warmth to the skin instantly rouses all the processes of life in certain prostrating conditions of disease, that cold at the zero of Fahrenheit, or mechanical irritation, reanimates the torpid hibernating animal, and sends up his temperature from forty or less to near a hundred degrees, that the first contact of solid food with the stomach diffuses a warmth over the cold surface of the famished traveler, or that tonics and stimulants do the same, that shame or anger suffuses the countenance, or fear withdraws the blood from the circumference to the centre and bathes the skin in perspiration or renders the urine redundant and the bladder irritable, that cold, when suddenly applied, as suddenly increases the excretion of urine, or the hot bath determines, as suddenly, its expulsion, that offensive odors, offensive sights, and even their recollection, lead to instant vomiting, or to purging, or to syncope, that an hour's change from one part of the town to another suspends pertus sis or promotes digestion or the healing of an ulcer, that one passion cures the most obstinate maladies, or another is instantly fatal,each, and all, I say, determine their effects either through reflex or direct action of the nervous system. Anatomy and experiment confirm what each phenomenon, and all united, proclaim the work of that mystic power, operating on those organic properties which are the moving springs of every action, the proximate cause of every effect; nor can another intelligible solution be rendered for a single phenomenon now expressed, or thousands of similar import, while every other must be in conflict with the pronunciations of Nature and the demonstrations of art. Nor will an attempt be made (an attempt that shall commend itself to the understanding) now, or hereafter, to controvert the philosophy which is here presented. The first step in its overthrow must be the overthrow of Nature. All must bow to this conclusion, however unacceptable to the humoralist, or unpalatable to the materialist (§ 1034, 1039, 1040, 1075).

897. It has been seen, also, that the fundamental philosophy of disease is perfectly simple, as also that which concerns its cure; that disease is essentially nothing more than a deviation of the properties of life from their natural standard, and a consequent corresponding change in the functions over which they preside; that the artificial cure consists in a restoration of those properties and functions by making upon the former certain impressions which enable them to obey their natural tendency to a state of health; that remedial agents of positive virtues operate like the truly morbific, but less profoundly in their therapeutical doses, and that the philosophy of their cure consists in establishing, in a direct manner, certain morbid alterations in the already diseased properties and actions of life which are more conducive to the natural tendency that exists in the vital properties to

return from morbid to their natural states.

898. It follows, therefore, when disease subsides under the influence of remedial agents, that it is only in consequence of the great law of recuperation, which is brought into sensible operation by the production of morbid states which are favorable to its development. But, if disease terminate fatally, it is owing either to morbid altera-

tions which transcend the recuperative tendency, or to physical obstacles which have resulted from the altered vital conditions. If disease subside without the intervention of art, it arises from the operation alone of that natural principle which has been established for the preservation of health, and the perpetuation of organic beings. Of this we have remarkable and striking examples in small-pox, measles, &c. For wise purposes, as we have seen, a principle of mutability has been established in the properties of life, and it is through this principle, which is designed for useful ends in the animal economy, that they are liable to be variously altered from their natural state by physical and mental causes; but it is this very principle which enables them to receive salutary impressions from remedial agents (just as morbific affect them), and to return to their natural condition.

899. The changes, therefore, to which the properties of life are liable, are almost of endless variety; depending, as we have variously seen, upon the nature of the operating causes, habits, natural and acquired temperaments, age, sex, &c.; and whenever they become diseased, they pass through a variety of progressive changes till they reach the acme of their morbid states. And so, on the other hand, when remedial agents begin their operation, a series of other changes sets in, and continues in regular progress until it ends in health. The pathological conditions, therefore, of any given disease are constantly

varying, and may require frequent variations of treatment.

900. It being only necessary to introduce a peculiar morbid change in diseased conditions that shall favor the operation of the natural tendency of the properties and actions of life to return to their healthy state, a very few remedial agents may be all that are requisite to the attainment of that result; while experience shows that our materia medica is encumbered with superfluities. Take a large variety of pathological conditions, such, for example, as are presented by inflammation, it is not necessary that a certain uniform change should be established by the remedies, but only such as shall favor the recuperative tendency. Bloodletting brings about one kind of change, cathartics another, antimony another, mercury another, and so on; while each of these agents may prove perfectly curative in many cases of all the modifications to which inflammation is liable from absolute mor bific agents. And yet it is obvious that each one produces changes peculiar to itself, while the changes induced by either will be as vari ous as the natural modifications of disease (§ 756, a). And just so it is in respect to the great variety of remedies which will tend to the cure of intermittent fever. This disease will sometimes yield to almost every thing in the materia medica, and may be suddenly broken up by an emotion of the mind. But every agent exerts changes in the morbid properties of life peculiar to itself, but such changes as enable the properties and actions of life to pass, afterward, through a succession of spontaneous changes under the restorative principle, till they end in health.* There is no other philosophy that will account for any of these phenomena, while they all concur in demonstrating its foundation in nature. Hence, also, I may add, what I have already endeavored to expound, the occasional salutary effects of alcoholic stimulants in the treatment of fever, and acute inflammations, and through which, in part, I have attempted to abolish the distinction between active and passive inflammation. In these exam

^{*} See Notes K p. 1119, L p. 1120, Em p. 1133.

ples, the alcoholic stimulants do but introduce morbid conditions that are favorable to the recuperative process, and are, therefore, so far on a par with loss of blood ($\frac{1}{2}$ 756, 851, 854, 892 $\frac{1}{6}$, 892 $\frac{1}{6}$, v, 1059).

901. Nevertheless, a distinction is very properly made into curative and morbific agents, however the former may be productive of disease, as they commonly are, in their medicinal doses when they do not correspond with the existing pathological conditions. Their absolute mode of action, however, is the same in all the cases; and although, in a general sense, remedial agents exert their salutary effects by inducing new pathological states, and are generally liable to produce disease when exhibited in health, these morbid states, when not excessive, are of a nature to allow the full exercise of the recuperative tendency. On the contrary, however, there is a class of agents which are more profoundly morbific, and whose results transcend the natural recuperative process. It is for the removal of these consequences that we employ the other class of morbific agents. Or, there are yet other means, like exercise, air, &c., whose influences are of the mildest alterative nature, and appear to co-operate in a direct manner with a tendency to restoration which had already begun; or, as in hooping-cough, where the restorative process is often easily introduced. Our remedies, therefore, are curative by substituting new pathological conditions, and nature does the rest; and it is only with a view to a right interpretation of their modus medendi that I have any disposition to depart from established phraseology, or to confound the operation of remedies with that of the ordinary causes of disease (§ 137, 143, 150–152, 177–182, 185, 893 c, d, 1059).

That what I have now stated as to the substitution of one pathological state for another in the cure of disease, and that this is the only contribution which nature receives from art, seems to be abundantly obvious; though the proposition which I have thus made appears not to have been a subject of consideration. As a change arises when efficient agents operate, and as that change, by the supposition, is not a restoration of the morbid to the natural state it is necessarily a new pathological condition. And so, also, of the unaided changes which Nature institutes, till the natural state is fully established. Bloodletting, and emetics, it is true, will be sometimes followed, as in fevers and in croup, by an almost immediate subsidence of the symptoms; but, during their rapid operation, they have only introduced new conditions of the pathological states which enable the morbid properties to resume, at once, a near approximation to their healthy standard.

It is certain that art can accomplish nothing more.

902, a. I now proceed to recapitulate the manner in which remedial agents produce their effects upon parts remotely situated from the direct seat of their application; and this, as I have formerly said, is through remote, contiguous, or continuous sympathy; the agents exerting their direct impression upon the parts with which they are in contact. Remote, and evidently, also, contiguous sympathy, are conducted by the nervous power through the medium of the cerebro-spinal and ganglionic systems; while, as I have also endeavored to show, continuous sympathy is independent of the nerves.* When, however, these enter into the structure of parts, as in animals, they have a certain contingent participation. But their primary connections may be wholly severed, and disease may be yet propagated continuously along the

*Continuous influence of these Institutes (§ 129 c, f, 498 a).

part to which they appertained; as we observe, also, in plants. It appears, therefore, that in these examples, the morbid condition is extended, in a continuous manner, from the organic properties of one point to the next in apposition (§ 185, 233, 461, $475\frac{1}{2}$, $647\frac{1}{2}$, 746c).

902, b. I have variously shown that the nervous power is capable of acting as a vital stimulus to the organic properties, is liable to be variously developed by morbific and remedial agents, and to be so modified in its nature according to the virtues of such agents, that it produces, more or less, in diseased parts, remote from the direct seat of the morbific or remedial action, the changes which the agents themselves would exert were they applied directly to the remote organs. The nervous power may be, also, equally determined with a morbific or curative effect upon the organic properties and actions of the great nervous centre; or upon any of its radiating parts. The philosophy is also exactly the same when one diseased part gives rise to disease in parts that are remote; and when disease in remote parts, that has been maintained by affections of other parts, subsides in consequence of the restoration of the latter, it is owing to the removal of a pernicious modification of the nervous power that had been constantly propagated by means of the latter upon the former (§ 409 k, 891½ k).

902, c. The type of the foregoing philosophy exists in various processes which are naturally going forward in the animal body. A single example of this nature is a key to the whole labyrinth. Thus:

"The whole system of respiratory nerves can be excited to action by irritation of any part of the mucous membrane, from the mouth to

the anus, from the nostrils to the lungs."

Mechanical irritation alone is adequate to the greatest variety of effect, as broadly stated in the foregoing law of sympathy. Tickling the fauces provokes vomiting, irritating the anus produces purging, and thus are the muscles concerned in respiration, and those of the stomach and intestine, and even the liver and the salivary glands, brought into unusual action by slight mechanical irritation of the fauces or anus. Irritate the same tissue in the nose, and the respiratory muscles are thrown into another mode of action; irritate the larynx, and another mode is excited; call up the recollection of the finger in the fauces, and the mind may determine all the sensible results of an active emetic, as set forth in § 500 i-m, o, 503, 514, 891½ k, 905 a.

There is the great principle. It is greatly the work of the nervous power, excited in one series of the cases by impressions transmitted from distant parts to the nervous centres, and in the other by the direct operation of the mind upon the same central parts. It is through that principle that emetics and cathartics produce their most sensible manifestations, and the same is concerned in all their less obvious influences upon every part but the intestinal mucous tissue, except as continuous sympathy may contribute a part of the influences which extend to the liver, &c. It is the same as concerns the respiratory movements, which, as I have said, may be regarded as an elementary exemplification of the most entangled operations of the nervous pow-The modus operandi may be repeated in its exemplifying relations to this subject. The point of departure, in the process, is the mucous tissue of the lungs, from which the impression is transmitted through the pneumogastric nerve, as well as through the ganglionic. to the brain and spinal cord (especially the medulla oblongata), where the nervous power is excited and reflected upon the organic properties of the muscles of respiration through the various motor nerves of those organs. These muscles are, in consequence, thrown into ac-

tion, and the thorax expanded (§ $233\frac{3}{4}$, 500 e, 514 l, &c.).

If the foregoing simple, demonstrable exemplification be duly comprehended, there can be no difficulty with all the rest. In the example of sneezing, as a consequence of the action of light upon the eyes (§ 514, l), the process is more complex, and shadows forth the far more intricate movements that are in progress,—the almost endless reflex nervous actions which are taking place,—during the progress or decline of disease, or those which are set up by the operation of an

emetic, a cathartic, &с. (§ 1040).—Nоте D р. 1114.

902, d. Physiological examples of the foregoing nature abound in the animal organization, and supply the most ample ground for the interpretation of the effects of remedial and morbific agents in their wide range of influences. The modifications of reflected nervous actions that relate to the respiratory system alone, as in coughing, crying, laughing, yawning, &c., are a fruitful field of inquiry into great and precise laws, and extensively applicable to the philosophy of medicine. The only difference is, that, when disease is established in a part, or when remedial agents operate, the organic properties of the part are altered in their nature, and, of course, the organic actions over which they preside. A specific impression, in the latter cases, is transmitted to the nervous centers, the nervous power more or less modified in a corresponding manner, and from thence reflected through other nerves, or other fibres, to the same or other parts, and, according to the nature of the modification, disease will be produced or mitigated in those parts. However complex, and variable, therefore, the phenomena, nothing can be more simple than the principle through which all these changes are produced ($\sqrt[5]{233\frac{4}{5}}$, $475\frac{1}{2}$, $647\frac{1}{5}$, $893\frac{1}{2}$).

902, e. When an emetic operates, the modus operandi is essentially similar to what happens in respiration. The mucous tissue of the stomach being the point of departure, a different influence is propagated to the nervous centres, corresponding with the nature of the exciting cause, with the special vital constitution of that portion of the mucous tissue, with the compound nature of the stomach, with the special relations of this organ to the central parts of the nervous system and to the respiratory muscles, &c. (§ 138, 149, 150, &c.), while the nervous power is also modified in its nature according to the peculiar virtues of the emetic (§ 227). The most sensible result, as in respiration, depends upon the reflection of the nervous power upon the respiratory muscles, while another current descends through the motor fibres of the pneumogastric and sympathetic nerves to the muscular tissue of the stomach. If the emetic operate also as a cathartic, then a new chain of actions is established, in the same way, upon the abdominal muscles, while a current of the nervous power is propagated upon the muscular coat of the intestines (§ $233\frac{3}{4}$, 889 a-f).

902, f. But, in the foregoing case, something more happens than in the natural processes. Here the exciting cause possesses peculiar virtues, is of a morbific nature, and it not only makes peculiar impressions upon the alimentary mucous tissue, according to the exact nature of its virtues, but it modifies the nervous power in a corresponding manner. If the stomach be the seat of disease, the direct impressions are the stomach be the seat of disease, the direct impressions are the stomach be the seat of disease, the direct impressions are the stomach between the stomach seat of disease, the direct impressions are the stomach seat of disease, the direct impressions are the stomach seat of disease, the direct impressions are the stomach seat of disease, the direct impressions are the stomach seat of the stomach seat o

sion upon that organ, or the change which an emetic may effect in its vital condition, will be more or less varied from what is exerted in a state of health. It may, therefore, prove curative to the stomach more or less by this direct influence (§ 514 b, 658). But the nervous power is also modified according to the impression produced upon the organic properties of the stomach, and is sent abroad, with alterative effect, upon various parts of the system. According to a law by which diseased parts are far more susceptible of influences from vital stim uli than such as are not diseased, the modified nervous power will fall with far greater effect upon the former than the latter. The organic properties and actions of one may be profoundly and permanently affected, while the latter are only moderately and very temporarily influenced. In consequence, also, of the deep effect which the modified nervous power exerts on the diseased parts, they may return, at once, to their natural state (§ 841, 2, b, 143, c, 148–151, 855, 895, 481 d).

But the milder influences which are set up by the nervous power upon parts in health, or in comparative exemption from disease, play, also, their part in the salutary process. If the emetic operate also as a cathartic, impressions are transmitted from the intestinal mucous membrane to the cerebro-spinal system, the nervous power developed and modified according to the nature of these impressions, and radiated abroad as when the result of the action of the emetic upon the stomach, and with effects corresponding to this new development and modification of the nervous power (§ 227–233 $\frac{4}{5}$, 514 h, 889 a).

Again, the skin is influenced in the foregoing manner, and this organ transmits that impression to the cerebro-spinal axis, and develops and modifies the nervous power accordingly, when it is, as in the other instance, reflected abroad, and is felt by various parts according to their degrees of susceptibility. Various other circles of modified nervous influences set in, and become too complex for analysis; but all may fall with one concurring curative effect upon the diseased susceptible organs. Thus every part may have an allotment in the curative process; as more distinctly expounded in foregoing sections (§ 143, c, and references, 500-514, 516 d, no. 6, 863 d, 889 g, 893 a, c).*

902, g. We thus see that when vomiting springs from the operation of tartarized antimony, and often from ipecacuanha, it is only one of the consequences, and a minor one, of the peculiar irritation of the gastro-mucous membrane. Other and far more powerful influences are determined, simultaneously, upon the organic properties and actions of distant and diseased parts (perhaps as distant as the most remote extremity), by the same nervous power that shook the respiratory organs during the act of vomiting. And often, indeed, does it happen that those influences are propagated with the most profound effect when the act of vomiting fails of being consummated; and nausea, alone, shall send with prostrating force the modified nervous power over the whole system; when we shall see it simultaneously bathing the whole surface with perspiration; pouring the saliva from the mouth; breaking down a tumultuous excitement of the heart and arteries; starting on the instant a torrent of bile, and an equal effusion from the intestinal mucous membrane; and, at the next moment, presenting a magnificent play of reflex actions for the evacuation of the fluids, after the manner of an active purgative,—these very effasions, also, instituting other circles of reflex action, which join in the great

^{*} See NOTE Cc p. 1132.

work of curative movements. Should vomiting now follow, then shall you speedily see the vital energies returning,—the cold, pale skin giving place to a florid hue and a warm perspiration,—the sunken features starting into the fullness of health,—the gastric suffering gone as a luxury obtained,—the general whirl of anxiety and distress converted into calm tranquillity,—the headache dissipated,—the twang of the croup, or the grunt of pneumonia, no longer sounding an alarm;—and, all this stupendous succession of events, from the beginning of nausea to the restoration of the vital energies and the near resolution of disease,—composing a most astonishing consecutive series of reflex actions,—may require less time than I have hastily employed in this general allusion to the subject. And now can it be entertained that this has been the result of absorption, or that the laws of chemistry or physics have had any connection with the phenomena?*

902, h. The foregoing may be taken as an example of the principle which concerns the modus operandi of all curative or morbific agents, whether physical or mental, and of all the developments of disease that arise as sympathetic consequences of each other. In respect to emetics, however, it should be considered that all do not produce the foregoing effects, and that with the exception of the act of vomiting, the results will depend upon the precise nature of the emetic, or the manner in which it modifies the nervous power and thus impresses the organic properties. This explains the difference in results between tartarized antimony, ipecacuanha, sulphate of zinc, warm water, tickling the fauces, the mechanical irritation of undigested food, the shock of a fall, of a surgical operation, sailing, whirling, offensive sights, offensive odors, loss of blood, and even their recollection; while the nature and effect of the greater number should lead the philosophical inquirer to pause at the physical doctrine of absorption, and survey the other difficulties with which it is fatally encumbered.

902, i. When the alterations, of a sympathetic nature, are more slowly produced, as when mercury induces salivation gradually, and brings the whole system under its influence, or when small, and repeated doses of tartarized antimony overcome inflammations of the lungs, &c., the nervous power is developed and modified at each successive dose, and the repetition of its reflection upon the organic properties of diseased parts remote from the stomach establishes progressive changes, till an absolute condition of disease may be induced in certain parts, as when mercury salivates; while the analogous influences which are exerted on parts already diseased supplant the naturally morbid states by others of an artificial nature, from which the organic properties are able to return to their healthy condition. But these impressions must be frequently repeated; for if the interval be long between the administration of the doses of such agents as only produce their effects in a gradual manner, the diseased conditions, not being placed in the way of the recuperative tendency, will throw off the artificial impression, and the original intensity of disease will be thus restored. The process which I am now considering is an example of the cumulative effect of remedial agents, some of which are much more remarkable than others, and the ultimate results are pronounced with varying degrees of suddenness. This is also influenced by peculiarities of constitution, or of susceptibilities of the organic properties to changes now under consideration; and therefore is it, that sal-* See § 409 k, 476} h, 514 -516, 943 a, 944 c, 1084

ivation may be speedily induced in one subject by less than a grain of calomel, while no amount of the remedy will produce this effect in others. And so of the morbific effects of digitalis; an agent, also, which exemplifies the suddenness with which cumulative agents may produce an explosion of disease, although no symptoms had admonished us of its approach. This principle concerns, also, the predisposition to disease which is formed by miasmata, the virus of smallpox, of hydrophobia ($\S 516 \ d$, no. $6.647\frac{1}{2},657 \ a,666,904 \ bb,1059$).

902, k. The permanent operation of the nervous power in particular parts of the animal fabric, as in the sphincters, supplies an elegant parallel with the foregoing uninterrupted influences of the same power as developed by remedial or morbific agents. This power operates as a perpetual stimulus to the organic properties of the muscles just mentioned, in the same way as the fæces and urine stimulate the mucous tissue. And now, if we mutilate the inferior part of the spinal cord, or observe the sphincter ani when relaxed in bad cases of apoplexy, or regard its condition when the spinal cord is merely divided, we shall see the relative bearing upon other organs of these two parts of the nervous system in their connected state, but with injury of the brain, and how the spinal cord is capable of an individual influence (§ 473-475, 476½-481, &c., 514 g, &c.).

902, l. When mental causes operate in the cure, or production of disease, they act directly upon the cerebro-spinal axis, and develop and modify the nervous power according to the nature of each mental affection; and, as in the case of physical agents, the nervous power thus developed and modified may be determined as well upon the organic properties of the brain and spinal cord, as upon other parts. The blow upon the region of the stomach, or the opening of a thecal abscess, which have destroyed life on the instant, operate in the same way as the paroxysms of anger, or of joy, which have been as suddenly fatal. In these cases the nervous power is alike reflected with a fatal effect upon the brain as well as other important organs (§ 479).

902, m. A more intricate example may now be presented relative to those natural means of cure which occur in a former section; such as change of air, exercise, &c. (§ 855). These are all positive remedies, and, of course, they have their modes of operating. One example will open the philosophy of the whole. How, then, does change of air suddenly arrest an obstinate form of the hooping-cough? There is gastric as well as pulmonary disease, and the mucous tissue of the stomach is preternaturally susceptible to the influence of many causes. The air exerts its impression upon the lungs, and upon the general surface of the body. But, there must be other agencies in operation before the lungs will experience relief. These agencies appertain to the nervous power, which is developed by the foregoing impressions, and reflected upon the stomach and other abdominal organs. If there be disease here, it is more or less relieved, and the more so the greater will be the ultimate salutary impression upon the lungs. The abdominal impression is transmitted to the nervous centres and the nervous power reflected with its alterative influence upon the pulmo nary mucous tissue, and thus ends the disease. The spasmodic action of the respiratory muscles is, of course, arrested by withdrawing the preternatural operation of the nervous power from those muscles, as a consequence of the subsidence of disease in the pulmonary mucous

tissue (§ 902, c). And so, when change of air promotes the healing of ulcers upon the extremities; and should they not be complicated with derangement of the abdominal organs, one of the sure evidences that the foregoing is the modus operandi of this remedy is the improvement of appetite which commonly precedes any manifest abatement of the remote affections. The same philosophy applies, also, to the control which air and exercise frequently obtain over phthisis pulmonalis (§ 514 c, 525 c, 527 b).* It is conspicuously seen even in the operation of morbific causes; and the two aspects of the subject go to illustrate each other (§ 657, a). The principle is of the utmost importance in medicine. Its laws are precise. Their knowledge will lead to a greater dependence upon the functions of organic life (§ 578, $890\frac{1}{2}$ d. But these problems lie in the depths of physiology.

903. It is important to consider the distinction between impressions which are made, in organic life, upon irritability and sensibility by vital agents, whether natural, morbific, or remedial. The latter property is the subject of impressions particularly in animal life; though it becomes more or less involved in organic, in all its natural modifications, by the accidents of disease. But the special modification which I have considered under the name of sympathetic sensibility performs the important part of transmitting impressions to the nervous centres when they give rise to sympathetic movements in organic life. Indeed, the whole rhythmic action of the organism is maintained by the transmission of influences from all parts to the brain and spinal cord through this modification of sensibility, and a consequent reflected action of the nervous power upon all the organs, as each may require the harmonizing influence of this great regulating property of the vital principle (§ 233\frac{3}{4}, 1037, b), through the potential sympathetic nerve.

The foregoing is the chief agency which sensibility exerts in organic life, and the nervous power no other than that of a vital agent, acting, like other agents, upon *irritability*, from which the influence is imparted to *mobility*. This we have also seen to be equally the case in animal life, when voluntary motion is performed. In all the cases, however, where *perception* is excited, either *common* or *specific sensibility* is more or less interested, though neither modification takes any part in the organic or animal movements ($\S 233\frac{4}{5},524\ d$, no. 7, $647\frac{1}{2},893\frac{1}{2}$).

If the brain, or any part of the nervous system, be the seat of disease, of irritation, &c., the preternatural development of the nervous power is, as we have seen, direct, and propagated directly, and with very various effects, upon distant parts. In this process the motor nerves are alone concerned, and therefore sympathetic sensibility is not brought into operation. It is exactly the second part of the process which takes place when influences are transmitted from one organ to another through the medium of the nervous centres. There is, therefore, no difference in the principle. The experiments of Wilson Philip, &c., illustrate the direct method (§ 477, &c.); the constitutional action of remedies the indirect, or by reflex nervous action.

904, a. In considering the philosophy of the effects of the nervous power it is important to regard its nature as liable to modifications from the slightest influences, both physical and mental. This is evinced by all the phenomena, is analogous to the natural and artificial modifications of irritability and sensibility; and according to its modifications, and other concurring causes hitherto expounded, it produces

^{*} See Note F p. 1114.

changes in the organic properties and functions; establishing or re-

moving disease, or killing in an instant.

I say, therefore, again and again, as more deeply seated than all things else at the foundation of medical philosophy, the nervous power is not only variously excited, exalted, or depressed, or modified in its kind, and produces influences upon remote parts according to these changes, but it is reflected upon particular parts according to their existing susceptibilities, the nature of the remote cause, and the part upon which the remote cause may operate ($\S 233\frac{3}{4}$). Thus, as I have said, one impression from cold, as a blast of cold air, or a drop of cold water upon the skin, will rouse the respiratory muscles. Another impression from the same cause will excite catarrh, or pneumonia, or pulmonary phthisis, or articular rheumatism (§ 649 b-d, 657, &c.). Mercurial ointment will determine the nervous power specially upon the salivary glands, and liver, and the same effects arise from the action of mercury upon the stomach. Cantharides, internally or externally applied, irritates the neck of the bladder. One degree of impression by tartarized antimony upon the stomach determines the nervous power upon the respiratory muscles, and vomiting is the consequence; while it simultaneously reflects the same power upon the skin as it does in smaller doses, and of which perspiration is a consequence,—and so on. But these examples embrace only certain parts of the influences in each case; while in others they are far more complex,—one sympathetic result becoming the cause of others, till, through a single impression upon the organic properties of the skin, various circles of alterative reflex nervous actions may be instituted. Narcotics induce peculiar modifications of the nervous power when they are administered by the stomach, and the power thus modified is not only reflected upon various distant parts with effects corresponding with its modifications, but especially, also, upon the organic and animal properties of the brain and spinal cord. Hence the obtuseness of the senses, and the venous congestions of the brain, which follow their improper administration ($\S 891\frac{1}{2}g, k$).

904, b. We have seen that hydrocyanic acid, strychnia, &c., will destroy life, when applied to the tongue, before one act of inspiration can be made, and that, when swallowed by man in speedily fatal doses the odor of the acid is indistinguishable in the blood, or within the organism (§ $350\frac{1}{2}$ p, 827 d). Wedemeyer and Müller testify to the fatal effect of one drop of the hydrocyanic acid, within a single second, when introduced into the eye of a rabbit. And so of strychnia. It is also allowed by Müller, who defends the doctrine of absorption in all cases, that from a minute to two minutes are necessary to one round of the blood's circulation. The case is a plain one; the contradiction obvious (§ 494, dd). Besides, the action of these poisons must begin at the instant of their contact with the living parts, and what is progressive throughout the entire second of time is physiologically the same as at the beginning of the second. Magendie kills "the most vigorous dogs" by applying to the fauces one drop of the hydrocyanic acid, "after two or three hurried inspirations." Pereira says that he "once caused the instantaneous death of a rabbit by applying its nose to a receiver filled with the vapor of the pure acid. The animal was killed without the least struggle." And so did Magendie. Pereira adds, that in cases of this nature, "the rapid action of the poisons seems

almost incompatible with the idea of their absorption."-Pereira's Mat. Med., p. 27, 242. The experiments by Stilling and Van Deen settle the question as to absorption (§ 494). Consider the action of opium. Apply it to the n ucous tissue of the intestine, and the local impression is such that it immediately arrests the peristaltic movements. Apply it to the surface of the brain, and it instantly lessens the action of the heart and capillary blood-vessels, &c. Now combine these phenomena, when opium exerts its direct action upon the stomach, and indirectly upon the heart, capillary system, &c., and consider the natural relations between the stomach and nervous centres. Take a substantial, physical fact, as supplied by the advocates of absorption. Thus:

"It is very singular," says Sigmond, "that a pill of opium, administered by the stomach at night, will be vomited up in the morning, after having produced its narcotic effect. This is an observation which Van Swieten originally made."—Sigmond's Lectures, &c.

My doctrine of alterative reflex nervous action clears up the obscurity, and admits of the only explanation (§ 512, b, $891\frac{1}{2}$ k).

"I am acquainted with a physician in London," says Sigmond, "who, on taking opium, although in a very minute quantity, will have over the surface of the body a scarlet efflorescence" (§ 891, e).—Ibid.

Is not this phenomenon due to the same principle as that which is concerned when indigestible food occasions analogous eruptions, or when they spring up, as in infancy especially, from gastric and intestinal derangements, or when the blotches of a surfeit vanish during the operation of an emetic, or as croup disappears under the same influence? Turn to the experiments of Philip, Alston, Hall, Stilling, Buniva, Van Deen, Kreimer, Procter, Girtanner, Johnson, &c., and they will be found to confirm my conclusion (§ 399, 483, Exp. 21, 484, 485, 828 b),* that they depend upon alterative reflex nervous actions.

The following are other facts which demonstrate the local operation of remedial and morbific agents, and the dependence of their constitutional effects upon the laws of reflex nervous action.

"An imponderable quantity of atropia," says Pereira, "is sufficient

when applied to the eye, to cause dilatation of the pupil."

Now consider the effect of this "imponderable quantity" in connec tion with the analogous effect of imponderable light (§ 514, k), and the modus operandi of the latter will be found to coincide with that of the former. The cases are remarkably parallel, and the more interesting as showing the transmission of influences through sympathet-

* In connection with what I have incidentally said in a former section of the advantages of opium in the cerebral congestion which is induced by the intemperate use of alcoholic liquors, and which constitutes a prominent part of delirium a potu (§ 891, r), I may say that we witness here, in the manner in which the irritability of the nervous tissues is relieved, and the subsidence of disease as a consequence, not only the special modification of irritability, according to the nature of the remote cause, but also the special adaptation as a remedial agent of what is morbific in cerebral congestions as induced by any other cause (§ 150, 151, 191, 650, 662, 686 b, 976 b, 1058 y).

But, although a knowledge of the remote causes aid us greatly in the treatment of disease, we may not proceed upon this consideration alone, as is commonly done, more empyrically, in delirium a potu. Opium rarely fails of being pernicious, in that affection, if there be much gastric or hepatic derangement, until this condition be more or less overcome. It is always useful to premise a cathartic, of which calomel should generally form a component part; and, in many cases, bloodletting is an indispensable remedy. But here, again, the exact pathology, and the complications of the disease, should be well ascertained, or bloodletting may prove as pernicious in some, as opium does in others. There are also certain states of the brain attendant on maniacs in which opium is bereficial; but we must be sure of the right, or we shall be sure to go wrong

eficial; but we must be sure of the right, or we shall be sure to go wrong U U

ic sensibility as pronounced in an expanded nerve and as implanted in the skin of the eyelid, or in the tunica conjunctiva, and therefore through different sensitive nerves, while in all the cases, the motor nerve, and the part which is impressed by the nervous power are exactly the same (§ $233\frac{3}{4}$). It is also worthy of remark, as exemplifying the modification of the nervous power by preternatural agents, that the motion of the iris is very different under the different influences of the remote causes (§ 74 a, $188\frac{1}{2}$ d, 514, l, 1042).

"It is a very interesting fact," says Sigmond, "that the application of hyoscyamus and belladonna to the eye was not applied to any practical purpose until a gentleman by accident applied a piece of the

herb to his eye, when the effect remained for three weeks."

He states, also, that a dilatation of the pupils may be produced by only approximating the leaves of hyoscyamus or belladonna to the eyes. This is a closer parallel with the effect of light than the prece-

ding statement by Pereira (p. 344, § 516 d, no. 6).

Observe how many individuals are liable to violent erysipclatous inflammation over the whole surface of the body from approaching only within a few yards of several species of rhus; while, on the other hand, many are entirely insusceptible of its action, as many are of

the constitutional effects of mercury (§ 585, b).

Here, again, is another fact, coincident with the foregoing, and which also elegantly illustrates the different natural modifications of the organic properties; even in different parts of the same continuous tissue (§ 133, &c.). "As an enema," says Sigmond (I quote from the advocates of absorption), "hyoscyamus, in any quantity, cannot be given." Authorities are quoted to show that it then produces delirium, and even apoplectic symptoms, and also when the "fumes were inhaled" (§ 827 b, 1066)—Lectures in London Lancet, Feby. 18, 1837.

The snuff which regales the nose, and the tobacco which equally delights the mouth, are violent poisons to the intestinal mucous tissue; and the constitutional results harmonize with the local effects in either case (§ 133, &c., 150, 151). Again, if remedial or poisonous substances act by absorption, why is tobacco smoke so innoxious when inhaled by the lungs, and yet so deleterious when swallowed, or when conveyed into the rectum? Most remedial agents, indeed, produce constitutional effects according to the natural vital modifications not only of the mucous, and other tissues of different parts, but of one continuous tissue, as the mucous membrane of the eyes, nose, fauces, œsophagus, stomach, small and large intestines, larynx, trachea, and lungs. Where would philosophy be; where our interpretation of these various consequences, if we followed the chemist in his physical views of life? What would tobacco affect in such a case? Would it nauseate by affecting chemical affinity, or cohesion, or elasticity, or would the nose or the mouth enjoy through any such properties of matter,—or would galvanism help our understanding? Is it through any such properties that we feel the smart when the fire burns? Pereira supply an important fact against his general doctrine of operation by absorption when he defends a moderate practice of opium smoking, -especially as the whole volume of smoke is drawn into the lungs?—(Mat. Med., p. 1293.) Shall we not rather look to what is known of the natural modifications of irritability in the mucous tissue of different organs? If opium offend the stomach, the principle is the

same as when urine excoriates the mucous membrane of the lungs, and thus produces the most violent reflex nervous actions. But the distinguished author above quoted shall lay down our principle himself. Thus:

"Sir B. Brodie," he says, "found that an infusion of tobacco, thrown into the rectum, paralyzed the heart, and caused death in a few minutes. But if the head of the animal be previously removed, and artificial respiration kept up, the heart remains unaffected; proving that tobacco disorders this organ through the medium of the nervous system only" (§ 484, b).—Ibid., p. 869. Also, Note B p. 1113.

Should we not rather say, through the medium of the brain in its connection with the organic nerve, while other parts may suffer reflex nervous actions through the spinal marrow, or even the ganglionic system alone. And now contrast with the foregoing peculiarities of tobacco and opium the fact that the inhalation of the fumes of hyoscyamus produces vertigo, tremors, laborious respiration, &c.; and that hydrocyanic acid, in the quantity of a drop, or in vapor, on account of the coincident relations of its virtues to the naturally modified organic properties of various parts, is instantly fatal, whether applied to the mucous tissue of the eyes, nose, mouth, stomach, or lungs. And so of the spirituous extract of nux vomica. If absorption be good in some of the cases, it should be equally so in the others. Consider, too, how the habitual use of narcotics reduces the susceptibility of the stomach to the influence of each one, respectively, and not to the others, and how the constitutional effects go on, pari passu, in the ratio of the local effects. And consider, also, how music assuages suffering, or the expectation of the dentist relieves toothache. And why, according to the doctrine of absorption, should not medicines produce the same constitutional effects when injected into the bladder, as when administered by the stomach? Are you doubtful as to the manner in which certain substances produce their constitutional effects when applied to the skin, as mercury and tobacco, for example? Consider the foregoing case of hydrocyanic acid; or how an issue relieves deepseated inflammation; or, again, how belladonna, or hyoscyamus, when applied to the lids of the eyes, as when to the stomach, produces dilatation of the pupils (§ 1066, p. 838, § $1057\frac{1}{2}$).

904, bb. Let us observe the constitutional effects of tartarized antimony when administered in small and repeated doses. This substance possesses, in a general sense, the power of lessening the irritability of the stomach (in relation to its own virtues), where the doses are small at first, and gradually increased. From this principle, indeed, results the necessity of increasing the doses as far as they may be borne without nausea, for the purpose of maintaining the same influence upon disease as is exerted by the first and smaller doses. In this way, in certain affections, as in articular rheumatism, we may sometimes rapidly increase the doses from the sixteenth of a grain to two grains, although the first dose shall have actually produced vomiting, while the two grains are borne without nausea. It is also certain that this progressive increase of the remedy, as far as may be admitted by the stomach, is indispensable to the full influence upon disease which was exerted by the smaller doses before the remedy had subdued the irritability of the stomach (§ 516 d, no. 7, 558, 578 d, 841).

Now were the physical, and not the physiological, doctrine true,

there should be no necessity for this regular and rapid increase of the doses. The nearer, indeed, each dose approaches the point of nausea so will the general arterial excitement, and local inflammations, be held in subjection; from which it is plainly manifest that the remote effects depend upon the amount of influence produced upon the stomach. And so of opium, and all the narcotics, and, indeed, of various other agents which are freely assumed to operate through the circulation. As to antimony, croup often subsides when nausea begins.

But again, on the contrary, we may obtain an exactly opposite series of results from tartarized antimony; by which we prove our proposition by the converse of the foregoing phenomena. We may begin the treatment by one eighth of a grain without producing nausea; but in an hour or two afterward, a repetition of the same dose nauseates the stomach, and prostrates the whole system. Again, at the same interval, we repeat the same dose and vomiting ensues, accompanied by still greater constitutional effects. We then reduce the quantity to the twelfth of a grain and again we have nausea and vomiting, with still greater constitutional results. We go on to reduce the dose in this manner, and, as I have witnessed in adults, it has been necessary · to diminish the quantity to the thirtieth part of a grain to avoid protracted nausea, and a general prostration of the system. Here, then, the remedy not only continues to nauseate the stomach in greatly diminished doses, but, as in the opposite case, there is a constant ratio between its impression on the irritability of the stomach and its constitutional influences and its special effects on diseased remote organs. However the dose may be diminished, so long as it impresses the irritability of the stomach, it breaks down the general arterial excitement, and often overthrows inflammation just as fully, and rapidly, as when two grains are administered with a similar effect upon the stomach. Nor is this all which antimony opposes to the doctrine of absorption; since in the cases first supposed, when it finally produces nausea after repeated and gradually-increased doses it does not reduce the irritability of the stomach after that dose, as after the beginning of the remedy, and when it did not produce nausea. On the contrary, the gastric irritability is now brought up to a full relation to the remedy in that last dose, where it either remains permanently for some time, or is quite as apt to increase in susceptibility to the antimonial influence, so that it may be necessary to diminish the next following dose to avoid a renewal of the nausea, and perhaps vomiting. In the mean time, the effects on the constitution, and on remote disease, are exactly conformable to the amount of influence upon the stomach. Clearly, then, its effects depend on reflex nervous actions.

904, c. Pereira has rendered our best standard work on Materia Medica liable to the objection which I am now considering, as he has, also, to that of reasoning from the effects of remedies on man in health, and even upon the naturally modified constitution of animals and plants, to the altered susceptibilities of man as they exist in disease. Of tartar emetic, he says, we do not know "the mode in which it produces its curative effect." And again, a universal opinion—

"Shall we deny the efficacy of bloodletting in inflammation, of mercury in syphilis, of cinchona in intermittents, and of a host of other remedies, simply because we *cannot* account for their beneficial effects? The fact is," he continues, "that in the present state of our knowledge, we cannot explain the modus medendi of a large number of our best and most certain remedial agents."—(Pereira's Mat. Med.,

vol. i., p. 417. 1839.)

This supposed ignorance is mostly predicated of the failure of detecting the medicines in the circulation; but will it apply to such observers as explain their modus operandi on other principles, and in conformity with well-established facts? If "bloodletting be efficacious in inflammation, mercury in syphilis," &c., they are so through great and immutable laws; and shall we rest in ignorance of those laws because we cannot deny the efficacy of the remedies? Is it not this very common representation of the topics before us, and of the phenomena of living beings, which has led to so general a disregard of the great principles in medicine, and to the revival of the exploded creeds of the iatro-chemical and iatro-mechanical philosophers? Or is it any argument against the interpretation of the properties and laws of organic beings, of their modifications in disease, of the modus operandi of remedial agents, as set forth by one inquirer, that fifty different and conflicting systems have been projected by others? Such, indeed, must be the position of every disputed topic when universal truth shall ultimately prevail. The argument, therefore, however common, is necessarily fallacious (§ 892, \vec{b} , 905 $\frac{3}{4}$, 829, 830).

There is no objection to admitting that all remedial and morbific agents find their way, very scantily, into the circulation, excepting as it regards the matter of fact, and a respect for those principles which nature has ordained for their exclusion so far as to prevent their ingress in injurious quantities. No conclusions, as I have shown, can be formed from the effects of injections into the circulation; which are the rudest facts in relation to a topic of this nature. It therefore becomes the merest assumption to affirm that the minute proportions of medicines, which may force their way through the well-guarded portals of the organism, produce those remarkable results which we witness after their administration by the stomach; while we are met at the threshold of the inquiry by the clearest interpretation of their modus operandi in the perfectly demonstrable laws of sympathy, in a stupendous display of reflex actions of the nervous power in the natural conditions of the body, and as modified by a vast variety of experiments, and by the morbid processes that are perpetually before us.

904, d. Again, take the grand characteristics of the cinchonas, arsenic, calomel, and the whole group of agents for intermittent diseases. Of cinchona, Pereira says (after having expounded its operation as a tonic through the process of absorption), that in intermittent diseases its "methodus medendi is quite inexplicable."—(Ibid., vol. ii., p, 1002, 1006. 1840.) But, is not its mode of operation just as intelligible in one case as in the other? Does not the whole system of nature, where common results are concerned in any integral part, enforce the belief that the same laws are concerned in both cases; and do not all the relative facts in physiology, all that is known of the properties of life, and of the constitutional effects of vital stimuli of any denomination proclaim the fact, that nature is just as consistent in this instance as she is in the simple principles which determine the phenomena of gravitation, of chemical affinity, of the attraction of cohesion, of repulsion, &c., or, in more sensible physics, of electricity, of light, of magnetism, &c.? If we refer, as does Pereira, to the effects

of cinchona as a tonic upon the healthy system, we must explain the methodus operandi before we can apply it in the least to any paralle effects upon morbid and enfeebled states of the system. But we may not speak of "augmentation of cohesion of the organic mass," &c. (§ 890, 890½).—Ibid., p. 1002. These are only effects of an antecedent operation, in which the whole modus operandi consists (§ 842). But the mode in which cinchona produces its effects in the perfect organism being just as obscure as in diseased states, we start with our interpretation of its modus operandi in intermittents just as we do of the mode in which cinchona produces its fullest effects in health; or raises the vigor of the stomach, sharpens the appetite, and braces up the animal man, in dyspeptic affections.

Now the mode in which cinchona accomplishes these last results is no more obvious than its action as a febrifuge. One must certainly be as plain as the other, since the essential influences and changes are exerted upon the organic properties of living parts, which are governed by simple and immutable laws. To explain the operation of a given cause upon two principles where the results are of the same genus, and nearly of the same species, would be to disjoint na-

ture completely, and to render her a deformity.

With this fundamental principle, we move forward to the interpretation of the effects of cinchona when it exasperates or produces disease; and so of other morbific agents. All the results, as they vary from those which follow the ordinary stimuli of life, depend upon the mutability of the organic properties and actions. Upon these, morbific causes, like the natural vital stimuli, make their whole impression; but they go farther in that impression than the natural stimuli of life. That is to say, they make their impression so profoundly, and in virtue of their peculiar attributes, as to alter the natural condition of the organic properties and actions; and this alteration constitutes disease. All that follows are but mere "sequelæ." Remedial agents, as we have seen, are capable of doing the same thing; and when direct in action, they operate upon the same principle. for this reason, therefore, that they produce disease in the healthy organism; and when they contribute to the cure of disease, it is in virtue of that morbific action which they exert on healthy parts. They are a class of morbific agents, however, which produce only such diseases, in health (if not administered in great excess), as are of a transient nature; and when, therefore, administered for the cure of disease, they induce a morbid state more favorable than the pre-existing to the natural tendency of morbid organic properties and actions to return to their healthy standard (§ 892 b, 893, 901, 1059).

Thus we get at a common principle of the methodus operandi of cinchona as a tonic, as a febrifuge, and as a morbific agent; and it is equally applicable to all other remedies which possess absolute remedial virtues. This philosophy enables us at once to understand how arsenic, cobweb, opium, alcohol, mental emotions, and almost every thing else, are, like cinchona, more or less curative of intermittent fevers; and though the alterations which are directly instituted by these various agents are unlike in all the instances, and correspond with the peculiar virtues of each agent, each one induces such changes in the organic properties as enable them to take on their natural tendency toward a state of health,—some being more conducive than

others, and either liable to exasperate the disease. We thus see, also, how it is that our remedies must be well adapted to the existing pathology, or they will prove morbific; since their operation is as well regulated by the nature of the morbid conditions as by the virtues of the remedies (§ 79, 150, &c., 857, 890 $\frac{1}{2}$ d, 892 d). We must look for the reason of this ready subversion of intermittent fever to solidism and vitalism. We must regard nature in her recuperative efforts as strongly pronounced during the periods of intermission, and thus learn from her that the morbid properties of life may require but a slight impression to establish an unintermitting tendency toward a state of health (§ 177–182, 557 a, 756 a, 775).

That there is a methodus operandi, in all the foregoing cases, is too certain to be questioned; and such being the fact, it is quite a becoming occupation for the human mind to interrogate its nature; or as the Wise Man, "it is the glory of God to conceal a thing, and the glory of man to find it out" (§ 892, b, 905\frac{3}{4}).—Notes K L pp. 1119, 1120.

905, a. I will now present a comprehensive example which illustrates the foregoing doctrines. A seton, passed through the skin of the neck, removes inflammation of the eyes. In this instance, nothing can possibly enter the circulation, but the whole influence of the seton upon the eyes must be exerted through reflex actions of the nervous system. By tracing out all the effects of which this seton is capable we may show that it involves all the principles which are concerned in the production of disease and its cure (§ 63-81).

In the first place, the seton establishes an inflammation in the part of the skin in which it is inserted. Here we have the whole interpretation of morbific agents in producing their direct diseases. Like the seton, all others act upon the irritability of parts, directly or by reflex action, alter its nature, and involve the other organic properties in corresponding changes, when a change of function ensues as a consequence; and then may follow a variety of physical results.

Now let us consider the seton in its curative aspect, as it relates to the ophthalmic inflammation. The morbid state of the skin operates as a peculiar stimulus, the result of which is transmitted to centers of the nervous system, where it develops and modifies the nervous power, and reflects it through organic nerves (§ 893 a).* The intensity of the nervous power, thus developed, is not sufficient to alter the organic properties of any part excepting the susceptible ones which conduct the inflammatory affection of the eyes through their instruments of action, and therefore no sympathetic disease is produced. But irritability being preternaturally susceptible in the inflamed eyes, the nervous power operates with effect upon it, and alters the nature of that and other properties so as to enable them to return to their natural state; and thus the inflammation subsides (§ 150, 151, 854).

We will next see how this seton may become the cause of disease in other parts by reflex action, and we shall then, also, have the whole of the principle which is ever concerned in the development of secondary diseases; and we shall see, too, that the principle is precisely the same as that which concerns the curative effects of remedies when they operate upon remote parts through the medium of another part; as in the curative effect of the seton upon the inflamed eyes.

Let us, then, suppose that the seton is permitted to remain in the neck after it has accomplished the cure of the eyes, till, finally, it ex-

* In this curative effect, as in the case of vesicants (§ 893 c), centres of the sympathetic nerve are more interested than the cerebro-spinal axis.—Note Dp p. 1132.

cites a severe degree of inflammation in the surrounding skin. Byand-by, we find the patient beginning to lose his appetite, the tongue coats up, and other marks of a diseased state of the stomach set in. This organ, therefore, has become involved in disease in consequence of the neglected and irritative state of the seton. Still, however, the mischief is allowed to go on, and the eyes, which had been relieved by the seton, again become inflamed. The seton has been the essential cause of this round of phenomena; and since nothing can have been introduced into the circulation, from beginning to end, we must look to the nervous influence for the remote developments of disease, as in the former case for the curative results (§ 514, h). The seton, after the cure of the eyes, had taken on a higher and modified state of inflammatory action, and it transmitted to the brain and spinal cord such influences as developed the nervous power in greater intensity and a more morbific condition. This state of the nervous power, being reflected abroad, fell with greater force upon the stomach than on other parts, from its peculiar susceptibilities, and its close natural relations with the skin and cerebral system ($\S 233\frac{3}{4}$). The stomach has also the eyes much under its control, and the eyes are now particularly liable to be injuriously affected by reflex actions instituted by the stomach on account of their recent inflammation, which left them in a more than usually susceptible state. The stomach, therefore, in transmitting its morbid impressions to the cerebro-spinal axis, co-operates with those from the seton in increasing and reflecting a morbific nervous influence upon the eyes. Thus, like vesicants, setons are mobific when their action extends beyond the centres of the organic nerve (§ 893 c).

We have now to consider the natural tendency of the properties and actions of life to return from diseased to their healthy states. The seton, as we have seen, is the sole cause of the new developments of disease in the stomach and eyes, and these effects are maintained by keeping up the irritative inflammation of the skin. If, therefore, we withdraw the mechanical irritant from the skin, the inflammation of the part will subside spontaneously; and having thus removed the exciting cause of disease in the stomach and eyes, these parts, also, return spontaneously to their healthy states. Thus it is, also, that the irritation of setons, issues, blisters, &c., when applied over the joints, &c., for the removal of inflammation of the ligaments or other tissues, may, after having greatly fulfilled their purpose, ultimately keep up a degree of the disease, or increase its intensity. But, if the skin be now healed, the disease will subside spontaneously,—the very healing of the skin reflecting salutary influences. This is often verified by the effects of remedies when administered internally; disease being ultimately aggravated by the means which were at first curative, but again yielding with rapidity as soon as the remedy is discontinued. In all the cases, the ultimate subsidence of the aggravated conditions of disease is owing to the artificial modifications of their pathological cause. This recuperative law lies at the foundation of therapeutics, and it shows us that the first and greatest step in the treatment of diseases is to remove their exciting causes; when the natural physiological constitution may require no other aid from art (§ 853).

The only remaining consideration to complete the essential philosophy of the operation of remedial and morbific agents relates to the direct action of remedies in curing diseases of parts to which they

may be applied. If an emollient poultice, as it is called, or opium, or leeches, &c., be applied to the inflamed skin, they may hasten the subsidence of the inflammation. This is done by their direct alterative action upon the diseased properties of the part, as in the case of morbific agents; and in proportion to the subsidence of the primary affection may be that of the sympathetic diseases. But, the sympa thetic affections may be also hastened in their decline by the direct application of remedies to the sympathizing parts; or, we may contribute to the cure of the whole by addressing remedies directly to one of the organs which has been sympathetically involved, as to the stomach in the foregoing case; or, the sympathetic affections may go on independently of the cure of the primary disease, and require a distinct treatment; or, it may be necessary to cure them first, before the primary disease can be removed. The diseased state of the stomach, for example, in the foregoing case, may, in its turn, establish a morbific reflex nervous action upon the seton, and thus complicate the principle as to exciting causes, and institute a mixed condition of reflex nervous influences. This, in fact, is more or less the case, in most diseases, after the morbid state is propagated from the primary seat. In the example now stated all the diseased parts act and react upon each other, each becoming a point of departure for the development of a morbific nervous influence, and each affection, therefore, contributing to maintain and aggravate the others. Other organs join in, though perhaps not essentially disturbed, and take their part in the disease according to their degrees of affection, and more or less, also, according to their relative vital importance and constitutional relations; while the great movement of diseased action may be variously influenced by the contingencies which grow out of constitution, temperament, age, habits, external influences, &c. (§ 512, &c.).

And so, on the other hand, when the curative process begins, whether instituted by nature or by art, the whole organic system may concur in the salutary change which is started at a single point (§ 143, c, and references there). It is all the work of the physiological laws.

905, b. The vast advantages which are every where arising from warm poultices, and warm fomentations, both in the hands of the physician and the surgeon, lead me to advert still farther to the philosophy which concerns their effects, in the hope that it may not only tend to their more frequent substitution for powerful agents, or for the surgeon's knife, and, therefore, to a better appreciation of the recuperative law, and a greater reliance upon Nature herself, but that it may contribute light upon the fundamental cause of disease, and the reme-

dial action of all things else.

In what I have hitherto said of the foundation of disease in common physiological principles, and of the near approximation, in their pathological states, of all the varieties and modifications of inflammation, in connection with what has been variously and specifically stated of the common mode of action which obtains with all efficient remedies, from the vesicant to the sedative, it is evident that the remedial action of poultices, and hot fomentations, falls under the universal philosophy. From blisters and irritating cathartics we readily pass along an intermediate series of analogies that are represented by other agents till we arrive at tonics and stimulants. In a former section I was employed in endeavoring to show, through the operation of these last

agents, that there is no ground whatever for the distinction which has been made of inflammation into active and passive, or sthenic and asthenic, conditions (§ 733 f, 752-756). The example supplied by erysipelas, in which blisters and leeches may afford relief when applied to the inflamed surface, either separately or conjointly, is only another impressive evidence of the close approximation of the various pathological states of inflammation; and the variety in the remedial virtues of the curative agents which have now passed under review goes to prove that they operate merely by inducing conditions of disease more favorable to the recuperative process. Loss of blood produces one kind of change, cathartics another, tonics another, vesicants another, and so on; but each one induces a change from which the morbid properties are capable of passing to their natural state (§ 8923, b). These principles enable us to understand how a great variety of physical and mental causes will often succeed in removing some particular malady, as one or another may be brought into action at its different pathological phases, as in intermittent fever; and reconcile, also, those embarrassing contrasts which have led to many errors in pathology and therapeutics, as when tonics and stimulants remove inflammation, or when patients equally survive the treatment of gastro-enteritis by capsicum or lobelia, as practiced by the bold and unprincipled empiric. A more violent inflammation may be the temporary consequence; but it differs from the original in being modified by the peculiar morbific virtues of capsicum or lobelia, and in which modifications the diseased properties are sometimes capable of exerting their recuperative energy (§ 1059).—See Note Ee p. 1133.

This conducts me to a more circumstantial exposition of the remedial action of local sedatives, especially of those for which this section was designed. In the mean time, however, on looking at the group of local sedatives, as arranged in my Materia Medica, we find linseed, and bread and milk poultices, holding the very first rank, while sedatives of the most active virtues, such as stramonium, aconite, belladonna, cicuta, cyanide of potassium, morphia, opium, henbane, &c., follow the poultices and hot fomentations as inferior reme-

But this arrangement, like that of all other groups, is founded upon the supposed relative usefulness of the several agents in fulfilling the objects of each group, respectively. Since, therefore, emollient poultices and warm fomentations effect the greatest amount of relief, and are far more generally applicable in practice than all the rest, as local sedatives, they should hold the first rank in the arrangement, notwithstanding the activity of their virtues is immensely less than that of the other substances which I have mentioned. It is the effect of all, however, to lessen irritability and sensibility, and thereby to moderate or subdue inflammatory action. But many of the local sedatives go farther than this. They also affect irritability and sensibility, especially the former property, in their existing nature or kind, and, of course, induce a corresponding change in the kind of action. Now, it is this alteration in kind, beyond the mere sedative effect, which makes up the differences between the various agents of the group of local sedatives. Poultices and warm fomentations produce the least of this change in kind; their effect scarcely reaching beyond that of reducing an exalted state of irritability and sensibility, or of keeping it down

where it is liable to ensue. The acetate of lead follows next, in this

simple but most valuable effect.

The foregoing moderate influences, with little or no specific alteration in kind of the morbid properties and actions, is just what is wanted in a vast number and variety of morbid states, as in superficial inflammations, abdominal irritations, sprains, bruises, piles, &c., or as means of prevention in the hands of conservative surgery. There is nothing comparable, for these purposes, with warm poultices and warm fomentations. Their immense services in the healing art, I say again, should turn the attention of physicians and surgeons with increasing reliance upon recuperative Nature. Let us study the precepts as inculcated by the fathers of medicine, an imbodiment of which may be seen in three of the mottoes at the head of a former section (§ 894).—Note E p. 1114.

In respect to the poultices, &c., no doubt the moist heat exerts some slight alterative effect beyond that of simply reducing the exalted properties and actions of inflammatory conditions. But, all the other changes and results which take place are brought about by Nature, and

not by the poultices (§ 878, 891 i, 891 $\frac{1}{2}$ g-k).

If local inflammations, to which poultices and warm fomentations are applicable, have given rise to disturbing reflex actions, or to inflammation of other parts, these sympathetic results may subside spontaneously when the primary disease gives way. But the poultices have nothing farther to do with any of these great movements of Nature than simply to lessen the irritability of the inflamed part with which they are in contact. In conservative surgery, poultices have even less participation in all those terrible compound fractures and dislocations whose cure they enable Nature to conduct with but even little inconvenience to their subjects, and which, till in recent times, were doomed to the amputating knife. In all these cases, the simple agents are only instrumental in keeping down irritability, and thus preventing inflammation and constitutional disturbances. They act partly upon the principle of keeping exciting causes out of the way of Nature (§ 856, a).

Finally, a word as to the contribution which is made by these great remedies toward the resolution of those phlegmonous inflammations which are disposed to result in suppuration, or how, in other cases,

they promote that disposition.

If the phlegmon have not reached the turning point, as it were, of the inflammatory process, or when the formative is about passing into the suppurative stage, an emollient poultice, by lessening irritability, will be very likely to promote resolution, and thus to prevent the sup-

purative stage.

But, when suppuration has begun, Nature, herself, has taken on the work of cure, and an abatement of morbid irritability is the first recuperative change in this natural process. Now it is, therefore, that poultices, through their tendency to lessen morbid irritability, co-operate with the natural process, and thus promote suppuration (§ 733, 735 a, 862).

GENITO-URINARY AGENTS.

 $905\frac{1}{2}$, a. In consideration of what I have said of *Emmenagogues* (§ $892\frac{2}{3}$, q), and to illustrate yet farther the action of remedial agents, before entering upon the subject of bloodletting, I have concluded to

set forth the ground of distinction which induced me to assemble into two groups those agents which bear the general denominations, in my Materia Medica, of *Uterine Agents*, and *Genito-Urinary Agents*. By introducing, also, the several members of each group, along with the numerical order of arrangement, it will be farther seen how far the arrangement has been founded upon physiological principles, and how far it is adapted to the modifications which are presented by pathological conditions (§ 137 d, 872 b, 892 $\frac{4}{5}$ b, c). There will be thus, also, farther exemplified the relative specific relations of many remedial agents to certain tissues, or parts of a common tissue, and farther, also, by the recurrence of the same agents in different groups, their therapeutical capabilities in their aspect of compound virtues (§ 129, 135, 136, 137 b, c, 150, 151).

Uterine Agents, in the order of their value (numerically).—1. Secale cornutum. 2. Oleum ergotæ. 3. Cantharis vesicatoria. 4. Sanguisuga. 5. Guaiacum officinale. 6. Juniperus sabina. 7. Ferrum, et ferri sales. 8. Aloe socotrina. 9. Balsamodendron myrrha. 10. Hydrargyri sub-murias, etc. 11. Hydrargyri iodidum. 12. Iodinium. 13. Potassii bromidum. 14. Ferri bromidum. 15. Ipomæa purga. 16. Juniperus Virginiana. 17. Aristolochia serpentaria. 18. Ruta graveolens. 19. Ferula asafætida. 20. Sodæ biboras. 21. Mentha

pulegium. 22. Helleborus niger.

GENITO-URINARY AGENTS, in the order of their value (numerically).—
1. Copaifera multijuga. 2. Piper cubeba. 3. Cantharis vesicatoria.
4. Strychnos nux vomica. 5. Barosma crenata. 6. Abies balsamea.
7. Oleum terebinthinæ (pinus et abies). 8. Pistacia terebinthus. 9. Arctostaphylos uva-ursi. 10. Cissampelos pareira. 11. Laurus camphora. 12. Tinctura ferri sesquichloridi. 13. Chenopodium olidum.
14. Chimaphilla umbellata. 15. Cinchona officinalis. 16. Amyris Gileadensis. 17. Pistacia lentiscus. 18. Physalis alkakengi.

905, b. The foregoing assemblages suggest, by the remedial virtues of the several members of each class, respectively, a great variety of pathological conditions relative to the uterus in one case, and, in the same manner, the genito-urinary organs in the other. We have already seen how ergot is mainly useful in parturition; and its obvious effects through reflex nervous action supply a clear analogy for expounding the effects of the other agents (\$ 893\frac{1}{2}). The other members of the Class of Uterine Agents are such as are denominated emmenagogues, with the exception of the fourth. But, leeches should evidently follow cantharides, in the order of importance, as capable of yielding relief, not only in the next greater number of cases, but in very difficult pathological conditions of the uterus; while the high place which they occupy is significant of irritable and inflammatory, or congestive affections of the uterus which may often call upon their aid, and admonishes the practitioner to beware of most of the other agents which follow, It is not, however, to such cases alone that leeches to the perinæum are appropriate, but to many cases where menstruation has been long arrested by slight derangements of the uterus, as sympathetic consequences of gastric or other abdominal derangement, but where the influence of vital habit is such that neither cantharides nor the stimulating emmenagogues, if admissible, will affect the condition of the organ; though its susceptibility to these agents may be established by leeching (§ 137 d, 8923 q, 893 q). Should leeching, therefore, fail, it is appropriate that an emmenagogue which may now succeed, and often by itself, should stand next in the order of arrange-

ment; and of these, guaiacum is the best.

It need scarcely be said, that in the reference which I have made to emmenagogues in section $892\frac{2}{3}$, q, I embrace alone those which have been hitherto grouped together with a special reference to the symptom, and upon which the denomination has been founded (E ν in,

 $\mu\eta\nu$, month, and $a\gamma\omega$, to lead).

We soon come upon the ferruginous preparations, and these, again, are significant that the uterine embarrassment often grows out of indigestion, or, less frequently, that some primary affection of the uterus has been the sympathetic cause of a gastric derangement that reacts upon the uterus and maintains its pathological condition (§ 902 b, 905 a). But, it does not often happen in primary uterine affections that an appropriate treatment will not readily succeed; especially leeches if inflammatory, or, otherwise, cantharides, and the subordinate means. Such, however, is the disposition of the system, especially of the digestive organs, to sympathize with inflammatory, or irritable states of the uterus, that these cases soon become complicated, and we may then turn to the example of the seton for the principles of treatment, nor waste our efforts at unavailing attempts with emmenagogues addressed to the symptom, but let them be such as shall meet the uterine complications.

Where ferruginous agents are proper, so, also, in a general sense, is guaiacum, or some analogous means. But, the attendant gastric derangement is apt to be accompanied by constipation, which is more or less dependent on an associated functional derangement of the liver (§ 129). Aloes, therefore, properly follows next in the order; and, although it may affect rather specifically the mucous tissue of the uterus, urinary organs, and lungs, in its irritable states by reflex nervous influences, it acts as an emmenagogue mostly by contributing relief to hepatic disorder, augmenting the natural stimulus of the intestine, and, in other ways, removing constipation, and thus, also, the symptom (§

889 i, 889 l, 902 b, 1063 b).

The simple mercurial preparations, which follow as the tenth in order, equally admonish us, also, to keep our attention upon the pathological condition, and away from the symptom, excepting as it is very vaguely significant of some morbid state of the uterus which can be known only through other phenomena. The rank of this agent implies, also, its degree of utility, the ratio of its frequency in contributing aid, its adaptation to a variety of pathological conditions that may be complicated with the uterine derangement, and the probability that it may be advantageously associated with leeching, and only as a subordinate agent. It comes into use, especially, in inflammatory states of the uterus, or when hepatic derangement takes the lead, and is inobedient to milder treatment.

The next are the iodides of mercury, and the bromides of mercury are about the same; and, who does not see that their special reference is not to the uterus, but to some other visceral derangement; perhaps of a syphilitic, or scrofulous nature, or under those diatheses? But which, and how much, what the pathological shades, what the exact condition of the uterus, how far it receives and reflects sympathetic influences, are matters for critical inquiry (§ 894 b, 901, 902 b)

The union of mercury with iodine also suggests a general antiphlogistic treatment, and that, like the more simple mercurials, it may be

often associated with leeching.

Iodine or the bromide of potassium is wanted next, on account of the scrofulous diathesis, or other special conditions to which those remedies are adapted. It denotes that the uterine function is often suspended by chronic visceral disease which has gone on to disorganization, especially of the liver or spleen; though, in other cases, it supposes the same condition of the uterus as a primary affection (§ 892½). It may be only the indigestion so often incident to the scrofulous constitution which arrests menstruation, and often without much derangement of the uterine system; and here iodine contributes an important aid. The uterus surrenders as soon as the morbific reflex nervous actions are withdrawn. The bromide of iron may be often now called in advantageously (§ 150, 151, 894 b, 901, 902 b).

Jalap is wanted to carry out a decisive antiphlogistic treatment, which is occasionally demanded; sometimes for primary inflammation of the uterus, or again for some general plethoric habit, or some obstinate chronic gastritis, and where the functional derangement of the uterus is of very little importance. In many of these cases, general bloodletting should take the lead in the treatment; and the menses may start under the beginning impression of the remedy (§ 872 b,

 $892\frac{3}{4}$ b, c, 1060).

But, there are no cases which so constantly baffle the practitioner as those which are presented by the nervous temperament; and these are common (§ 601). A reference to the characteristics of that temperament will show us, at once, how it has happened that asafætida is the only agent that has been introduced with a specific reference to the symptom in this class of remedies. The whole body is so alive to reflex nervous actions, as disease may touch upon one part or another, and more profoundly as it may plant itself in greater force, that nothing can be now accomplished but through the precepts of the most enlightened medical philosophy. It is here, too, that we see most distinctly pronounced the complete possession which gastric derangements may take of the uterus, and overthrow its function, or where it may be interrupted by a sudden reduction of the temperature of the feet, or by a midnight frolic, or by drawing the habitual corset a little tighter. Now, too, any disturbance of the uterus, whether primary or secondary, reacts on most other parts, while they, in their turn, resent, as it were, the injury (§ 514, h, &c.). The treatment of these cases, therefore, may be as complex as the morbid sympathies. But, in a general sense, the best and often the only requisite emmenagogue will consist of a carefully-regulated diet, early sleep, free exposure to the open air, accompanied with a suitable kind of exercise, sometimes shower bathing, or, at other times warm bathing, removal of corporeal restraints, cheerfulness of mind, and a little rhubarb and magnesia to improve digestion, keep down acidity, and to help any sluggish state of the bowels. We must repair the constitution of these patients; and there will then be no difficulty with the symptom. It has been a neglect of the means, the neglect of pathology, and the name of emmenagogue, which have led to most of the failures of art, and have contributed to swell the nomenclature of "nervous diseases" (§ 659, 855, 856, 878, 902 m). Nor has the fashion of "Specialities,"

which forms one of the perversions of morbid anatomy, as handed over from France, and one of the roads to distinction and practice, been wanting in a liberal contribution to the very errors which it professes to reform. The principal observers are generally able, always industrious; and would they but merge their tangible, isolated objects in the comprehensive philosophy of medicine, they would give an impulse to science, and a direction to practice, which would bring honor to themselves, and bestow a service on mankind. We need no better demonstration of this than what I have just been saying of the nervous temperament (§ 701, 960 c).

905½, c. We come, next, to the Genito-Urinary Agents, where a great variety of remedial virtues occurs, but, unlike the case of emmenagogues, where all have a special reference to the genito-urinary system, with the uterus excepted as to its relations to cantharides and chenopodium. It is a group, therefore, which illustrates, throughout, what is denominated specific action, and exemplifies extensively the special modifications of irritability in different parts of the body

(§ 133, &c., 150, 191).

When, therefore, these agents are employed with reference to the genito-urinary system their local action is alone contemplated. The favorable changes which they induce are of a direct nature as it re spects that system of organs; and they do not, therefore, contribute relief by effecting the removal of diseases situated remotely from

those parts (§ $905\frac{1}{2}$, b).

Hence, it is readily seen how liable to misapplication such a group of agents must necessarily be without a sound knowledge of physiology, and an enlightened view not only of the general conditions of disease, but of the pathological varieties and shades of difference which are constantly presented by any given common form of disease; especially of inflammation (§ 639 a, b, 650, 662, 669, 671-674, 718, 722, 819 a, motto, no. 7). To such an observer the assemblages in the various groups are peculiarly valuable, and for such, indeed, are they alone designed. To him, each group, each remedy, every virtue in a compound remedy, and whether so by Nature or by art, has its individuality, which is recognized as the eye glances from one agent to another, while it carries along an associated recognition of a vast variety of pathological states, and a just appreciation of the relative therapeutical value of the various means which may be the subjects of his transient inquiry. But, the group now under consideration being exclusive, and, withal, not as liable to morbific effects as are most other classes, the uninformed has less chance at mischief than when he approaches the cathartics, &c.; where physiological and pathological knowledge is far more important.

It is readily seen, therefore, that one, or more, of the foregoing agents may be exactly adapted to a given modification of disease, inflammation, for example, affecting either the mucous tissue of the vagina, or of the bladder, or of the urethra, while it would be very unsuited to another modification; and, from what we have seen of the natural modifications of the vital constitution in the same tissue as it may occur in different compound organs, and in different parts of a continuous tissue as it traverses different organs (§ 134–137), it is evident that great circumspection is often necessary in the application of these agents; and farther, also, that what may be immediately useful

in some special state of inflammation as affecting one of the several parts of the genito-urinary mucous tissue may be detrimental in an apparently coincident form of the same disease in either of the other parts; and vice versa (§ 137 c, 150, 151, 870 aa). Here we have, for example, amenorrhæa, as considered in the foregoing section, depending on active inflammation of the uterus where general bloodletting may be demanded, and may be sufficient; but, in event of its failure to establish menstruation, cantharides, which would have been otherwise pernicious, may now complete the requisite instrumentality

of art (§ 137 d, e, 143 c, 859 b, 863 d, 867, 871, 905 b.)

Take, next, the same agent as the best internal remedy for leucorrhæa. Here, again, the inflammatory states, which constitute that affection, vary constantly, not only as to force and habit (§ 535, &c.), but more greatly in the absolute modifications of inflammatory action. For all this knowledge we must go to our general principles, then to all the minutiæ of symptoms (§ 685, 686). Among the last none are so important as the exact character of the discharge, which varies, by gradations, from purulent to mucous, and from this last to a bloody, or a brown watery, or a more simple watery fluid; just as we have seen of analogous phases in the condition of ulcers, or of intestinal inflammation (§ 693, 740). Now, it is clearly wrong to treat any one of these several conditions exactly in the same manner; and where the differences are broadest, so also must be the variations of treatment. In indolent states of the disease, and where the discharge is mostly purulent, if the general health be tolerably sound, we may proceed, at once, to the exhibition of cantharides; and, as soon as slight strangury takes place the disease will generally surrender. But, should it, in the cases supposed, refuse to submit, or should the individual be insusceptible of the special action of cantharides, as will commonly be denoted by the failure of its effect upon the bladder, we may safely, and commonly with certainty of success, resort to vaginal injections of the best nitrate of silver, in proportions varying from three to eight grains in an ounce of water. But, if the discharge consist of mucus, or any other than the puriform matter, cantharides will aggravate the affection, and the nitrate of silver, at most, will do no good. If it be mucus, it denotes an intensity of inflammation which calls, at least, for a simple vegetable diet, and probably for leeches to the perinæum, along with the general antiphlogistic treatment. In these cases, therefore, we have nothing to do with the genitourinary agents. Equally inapplicable, also, are they to those pathological states from which result the watery discharges; and here we are completely thrown upon the special circumstances of every individual case, and upon the general principles of the science.

This last remark leads me to another more important than the rest; namely that all the pathological varieties which go to constitute the symptom may be variously complicated with morbid affections of other important organs, especially those of the abdomen, through alterative influences of reflex action of the nervous system. This, indeed, is always the case in the watery discharges, almost always in the mucous, and very often in the puriform. In all the cases, too, the vaginal or uterine affection may be entirely a sympathetic result of primary disease in the digestive organs; and such is usually the case where the discharge is of a watery nature. We may be sure, however, that

the sympathetic affection will react upon the system at large, especially in the more intense form which is denoted by the mucous product; and this, whether the genital affection be primary or secondary.

Here, then, we must apply ourselves to the general health, attack what may be the citadel of disease; but, to do this efficiently, and that our prescriptions may carry with them the combined virtues of tuto, cito, ct jucunde, the practitioner may not undervalue the Institutes of Medicine.

Whenever the uterus is the seat of disease in its mucous tissue, like all other organs which may be especially affected in one of its parts, the other component parts suffer, more or less, sympathetically (\S 138, 141 b, 514 f, 528).

A common form of discharge takes place from the uterus which is more or less of the nature of lymph. Here there is pretty high inflammation, as well as obstinate. It calls, of course, for general bloodletting, leeching, &c. I say nothing of cases requiring local remedies.

Copaiva is the first among the agents in the group before us. This denotes the frequency with which it is called into use in the treatment of gonorrhea, and its relative value for this specific purpose. Cubebs follows next; and as two agents of similar virtues in relation to a specific object, and of nearly equal pretensions, and both of them stimulant, lead off in a general class of remedies, they are, by the position they occupy, standing mementoes of the frailty and vulnerability of man, and incentives to study well the varying conditions of gonorrhea. Here we have rarely more than a local complaint for our professional skill; and yet, how much suffering is inflicted, how many made wretched in their domestic relations, by the indiscreet use of these two valuable agents, and by astringent injections! The haste of the patient may be always moderated, or conquered, by firmness in the appropriate means, and the practitioner rewarded in conscience, and thanks, where he may elect, for the preliminary treatment, that antiphlogistic plan which will speedily prepare the way for the remedies of more local action, if it do not in itself succeed. Here, too, we may notice in the contingent circumstance, as in all other groups, that when gonorrhea yields to general or local bloodletting, or to cathartics, or to water gruel and perfect rest alone, another of the multifarious demonstrations of the common mode of Remedial Action.

905\frac{3}{2}. In concluding the subject of Remedial Action as hitherto expounded, and before entering upon that of loss of blood, I shall take the liberty of protesting against the unreserved imputation of ignorance as to the modus medendi of remedies, and of which I have quoted some examples (\\$ 904 e, &c.). It is true that they who allege this ignorance cultivate the humoral and chemical doctrines, ignore all distinction in the powers by which the two kingdoms are governed, and satirize the laws of the nervous system if supposed to involve any thing more than chemical action. These positions certainly imply, as far as they reach, all the acknowledged ignorance, and the objection, therefore, which I now raise is against the imputation of this ignorance to those who have taken the trouble of informing themselves about the things which they profess to understand. They object to a degradation to such a level. Where the ignorance exists its confession is laudable and useful.

THE INFLUENCES AND MODUS OPERANDI OF LOSS OF BLOOD,

Considered with a Reference to the practical Application of the Remedy and the various Circumstances of Disease.

906, a. "The serous portion of the blood, or even pure blood, may escape from the over-distended vessels, just as water transudes through the permeable sides of a vessel, in which it suffers compression. To this source are to be referred several hemorrhages and dropsies it suffers compression. To this source are to be referred several hemorrhages and dropsies produced by simple transudation in a tissue mechanically congested; and although these affections have really nothing active in their nature, yet are they considerably diminished, and sometimes altogether removed, by bloodletting, which, in such cases, acts in a manner purely mechanical, by removing from the vessels the fluid by which their parietes were kept in a state of over-distintion."—Andral's Pathological Anatomy.

b. "If bloodletting be considered in a mechanical light, as simply lessening the quantity of blood, I cannot account for its effects; because the removal of any natural mechanical power can never remove a cause which neither took its rise from, nor is supported by it."

HINTER on the Blood and Information

-HUNTER on the Blood and Inflammation.

c. "It is a great modern improvement in the practice of the healing art, in bleeding for the cure of inflammation, to take the blood away as quickly as possible; since intense in flammations of the brain, lungs, bowels, &c., are equally removed by faintness, whether it happens after the loss of ten ounces of blood, or of fifty; or even, as sometimes occurs, when it happens without bleeding at all, after merely tying the arm in preparation."—ARNOTT's Elements of Physics.

d. "If we have to deal with an extensive and violent inflammation, we do not abstract blood here."

blood by a minute opening; we make a large orifice, or we open a vein in both arms at the same time; we place the patient in an erect posture, and endeavor to produce deliquum. It sometimes happens that the patient faints from fear, or before any considerable quantity has been lost; and this faintness, as Dr. Arnott remarks, answers as well as that which results from venesection" (§ 960, a).—Graves, in London Med. and Surg. Journal, vol. iii., p. 391.

e. Ad extremos morbos extrema remedia exquisite optima."—HIPPOCRATES (§ 960 h).

906, f. Whether the father of medicine, or his latest descendants, be right or wrong in their medical precepts, especially in relation to the therapeutical uses of bloodletting, it will be an object of the present inquiry to ascertain (§ 3763, a). The contrast of views, especially when we consider the details inculcated by Hippocrates in respect to loss of blood, as well as other remedies, suiting them all to the exigencies of disease, or leaving the whole work to Nature, and, with all his enlightened precaution, regarding the loss of blood as the remedium principale, renders it, I say, an object of deep interest to de-termine the nature of the right, and, in so doing, to ascertain also how far philosophy and practical habits have outstripped the Ancestor.

We may also, perhaps, come to some determination whether a knowledge of the principles upon which bloodletting operates be worthless, or necessary to its just and intelligible use (§ 893, n). Whether we should know what absolute influences it exerts, or how it exerts them, before we can appreciate its applicability, and its appropriate extent, in many important morbid states where the remedy may be more demanded than in other conditions whose phenomena

clearly indicate its necessity (§ 857).

Perhaps, also, it may be useful to science, as well as humanity, to strip this remedy of its mechanical interpretations, and to place it upon the dignified, practical ground of the physiological institutions of organic Nature, which, if unacceptable to the materialist, will, at least, engage his attention as a philosopher.
906, g. Before entering upon the investigation of this subject I

take leave to say, that the modus operandi of loss of blood, as set forth

in this work, is exclusively original with myself. If there be any merit in the philosophy, its abuse and misrepresentation by the British and Foreign Medical Review, and the Medico-Chirurgical Review, of London, entitle me fully to all the proprietorship. Whatever is said of the vital influences of the loss, and of the whole theory of the associate influence of the nervous power, appeared for the first time in the Medical and Physiological Commentaries (§ 222, b). Copyists, it is true, have appeared, especially of the accumulated facts, without the slightest reference to him who performed the labor (§ 435, b).

Although, therefore, the same philosophy, and the same practical applications of loss of blood, are preserved in the Institutes as set forth in the Commentaries, they are now rewritten and presented in another shape, with greater brevity, and with reference to that systematic order which shall best subserve the young Inquirer. The same is also true of other subjects which may have been investigated in the Commentaries.—See Rights of Authors, p. 912.*—Note Wp. 1127.

907. Notwithstanding the practical importance of a distinct apprehension of the modus operandi of loss of blood, it should never be the leading indication for its use; but only subservient to the suggestions of the morbid phenomena, of pathological principles, and of experience. The just application of the remedy should be determined by these combined considerations (500 m, 688, 694\frac{3}{4}, 826 cc, Note LL).

908. Again, by taking a comprehensive view of the direct influences of loss of blood, we shall not fail to discover the close analogy of its modus operandi with that of all other remedies, and that it reflects an important light upon the whole ground of remedial action; while its loss involves in its effects some principles peculiar to itself.

909. The hypotheses which have hitherto prevailed respecting the operation of loss of blood have been, for the most part, mechanical; but I have demonstrated in my Essay on the Philosophy of its Operation, that the effects of blood-letting are wholly incapable of such explanation. Nevertheless, even dry cupping, and ligatures to the limbs as extensively inculcated by Erasistratus and facetiously commemorated by Galen, are again restored as substitutes for loss of blood (§ 1004 c).

910. The numerous advocates of the mechanical doctrine of inflammation and venous congestion predicate their views of the operation of bloodletting in conformity with the supposed existence of passive relaxation of the affected vessels, and stagnation of blood within them, and extend the hypothesis to the hot stage of idiopathic fever. The philosophy, therefore, is vitiated by the pathological views upon which it is founded. Moreover, were the doctrine of debility (§ 569), passive relaxation of the vessels, and stagnation of blood, correct, it is evident that not only such relaxation, but that the stagnated and coagulated blood, would not be suddenly removed by diminishing, to any extent, the general circulating mass, as is constantly witnessed in inflamed parts; while, also, were such a physical impossibility within the power of the remedy, those vessels would immediately become again congested, and the more so from the prostrating nature of the remedy (§ 935, 977).—Note Dp p. 1132.

911. General bloodletting, cupping, and leeching, manifest some important differences in their effects, but operate upon modifications of a common principle. A knowledge of these modifications is necessary to a right administration of the remedy as it respects one or

^{*} The Works of Authors quoted in this Essay may be found in the "Commentaries.

the other modes of abstracting blood. Neither method has been

founded upon any rational principle.

912. How, then, does bloodletting operate? How are diseased parts immediately and permanently unloaded of their blood, in some instances by the abstraction of two or four ounces of blood, when, in other cases, under apparently the same circumstances, a great extent only of the remedy will effect the same result? Why, in such cases, may the former quantity induce syncope, when the latter has no such effect? "Syncope," says Robert Jackson, "occurs sometimes in yellow fever from the loss of a few ounces of blood, sometimes scarcely from the loss of six pounds." Why does this coincidence obtain with so many other remedial agents? Why do we see the redness of an inflamed eye give way permanently while the blood is flowing from the arm, and why does the same change take place as rapidly, and even more perfectly, in any of the great organs when equally inflamed and loaded with blood? Why may the action of the heart be weakened by small quantities of blood taken by leeches, when larger quantities would be required to produce a similar effect by venesection (§ 516 d, no. 6,557,686 b,756 a,775,889 l,893 a,c,900,904 c,921,1059)?

Now it is obvious that the foregoing results can be explained only upon the physiological principles which I am about to set forth; while there is not one phenomenon attending all the diversified effects of loss of blood that is not susceptible of a clear interpretation upon those principles—an interpretation, too, which corresponds with all that I have said of the modus operandi of every other remedial and morbific

agent-nay, even with the natural stimuli of life.

913. The inquiry now proposed will extend from the beginning of the physiological influences, through their gradations, to their consummation in syncope. It will be also accompanied by practical illustrations, and by exemplifications of the various conditions of disease to which the remedy may be appropriate.

1. LEECHING.

914. It will be most useful, in the first instance, to observe the phenomena, and deduce the principles, which attend the direct abstraction of blood from those extreme capillary vessels which are the instruments of all morbid processes. Leeching, therefore, is first in order; the physiological effects of which may be divided into seven stages. Observe, also, that the vessels are torn not cut as in cupping.

915. 1st. The earlist effect of loss of blood consists in a contraction of the blood-vessels. This is universally true of all modes of abstract-

ing blood (§ 944 c).

In leeching, an impression is first exerted upon the organic properties of the extreme and capillary vessels of the part by the direct abstraction of their natural stimulus, the *pabulum vitæ*, as also by the long-continued suction of the leeches, and by the subsequent effusion of blood. These causes institute a change in the vital state of the vessels (§ 189, 498, 930, 944 c).

916. 2d. A vital contraction follows immediately, as the consequence, in the extreme and capillary vessels of the part to which leeches are applied. The removal of their natural stimulus is necessarily felt by the highly-susceptible organic properties of the small

vessels (§ 188, 189, 191, 410, 411, 746 c, 931, 935 b, 1040).

917. 3d. Then follows, by continuous sympathy and reflex nervous action, a propagation of the foregoing changes to the entire system of extreme and capillary vessels throughout the body. This arises from the capillary series possessing, every where, an organization and function of a common nature, and from their exquisite sensitiveness to the nervous power (§ 129 d, e, 141, 222-232, 482, 525, 526 a, 935 b).

918. 4th. The larger vessels, sooner or later, participate, sympathetically, in the contraction. This sympathy, however, begins as soon, at least, as the general capillary system feels the foregoing in-

fluences (\S 944 c).

919. 5th. A partial reflex nervous action begins upon the heart as soon as the changes have somewhat advanced in the capillary vessels to which the leeches are applied, and a rapidly-increased amount of this cardiac influence ensues as soon as the whole capillary system is involved in the contractions which the leeches institute at the place of their application (\S 498 f, g, 524 a).*

The effect, as expressed in section 917, is originally propagated along the extreme vessels by continuous sympathy, but reflex action is soon brought into operation, when both denominations concurtogether; but it is chiefly by reflex nervous action that the heart is influenced (§ 933. For continuous sympathy see § 129 c, f, 498, 746 c, and INDEX II).

920. 6th. Such are the simple elements of the processes which take place in leeching. But, during their progress they become more or less compounded. The reflex nervous influence which is propagated from the extreme to the larger vessels reacts from the latter upon the former, and this reacting sympathy increases the contraction of the small vessels. So, also, as soon as the vital changes in the extreme vessels throw their reflex nervous influence over the heart the changes which take place in this organ reflect back a sympathetic influence upon the extreme and capillary vessels, by which their power over the heart and larger vessels becomes multiplied (§ 514 h, &c., 526 a, 934).

This complex circle of reflex nervous actions continues to advance till the heart becomes overpowered in its action, and syncope

takes place ($\sqrt{222-233\frac{4}{5}}$, 498–514, 893 a, c, 894–905, 1039).

921, a. 7th. An artificial change being instituted in the extreme vessels to which leeches are applied, where the organic properties are most strongly pronounced, and that change being more or less permanent, it continues to excite a powerful reflex nervous action upon the whole capillary system, and thence upon the heart, long after the blood has ceased flowing (§ 514 g, &c., 516 d, no. 6, 939).

921, b. It is for this reason (no. 7), and this only that the powers of the general circulation may be sometimes more prostrated, and be longer maintained in a state of prostration, by the loss of four ounces of blood by leeching than they might have been by the abstraction of sixteen ounces of blood from a large vein, or by eight ounces taken

by the process of cupping (§ 514 g, 930, 939 f, 944 c).*

921, c. For the same reason, also, syncope sometimes comes on only many hours after the discharge of blood has ceased. Stimulants, too, may but slowly rouse the general circulation, because the prostrating influence of the artificial change in the extreme vessels cannot be as soon overcome as when syncope is produced by general bloodletting, where no such specific impressions are made (§ 514 g, 516 d, no. 6), and therefore no persisting reflex nervous influence.

^{*} See sensitiveness of the heart to the nervous influence at § 500 m, 826 cc, 829.

922, a. It is owing to the peculiar nature of the change established in the vital condition of the *lacerated* vessels, by leeching, that the blood continues to flow out for many hours. The process thus instituted must be somewhat analogous to that of secretion, and clearly allied to the hemorrhagic action which nature institutes, though gen-

erally more prostrating than the natural process.

922, b. There is, however, a remarkable difference between the direct effects of leeching and spontaneous hemorrhage, in respect to their force; the former subduing inflammation and congestions more fully and speedily than the latter. It is rare that an equal quantity of blood spontaneously effused impresses the system with a force equal to that from leeching; while large capillary hemorrhages are daily occurring without very sensibly reducing the animal or organic powers, and where, too, the quantity of blood effused is so prodigiously great that it cannot be safely imitated by art under the same circumstances of disease. The nervous power is differently developed.

Although, therefore, in these cases, nature institutes a change strikingly analogous to that of leeching, it is not of the same specific nature. In spontaneous hemorrhage, too, nature sets up, for her own safety as it were, a special modification of action in the system at large that shall sustain its powers under the enormous losses of blood which are often necessary, by the natural process, to the cure of inflammatory and congestive diseases (§ 136 c, 150-152, 524 a, d, 890 e).*

923, a. Besides the foregoing play of vascular sympathies, a strong impression may be propagated by the whole organ to which leeches are applied to another organ with which it has strong natural sympathetic relations. In low inflammations and venous congestions of the liver, four ounces of blood taken from the verge of the anus by means of leeches may break up those obstinate hepatic affections, when twice as much from the skin over the region of that organ may produce far less effect. Here the specific impression is propagated, in part, along the mucous tract of the intestines, in the manner expressed in sections 498, f, g; and this continuous sympathy gives rise to alterative reflex nervous action, the former of which is my continuous influence (\S 498 a).

923, b. But, again, it is true in a more limited sense, that the influence of leeching may be propagated along the large blood-vessels to the parts in the vicinity where there is a direct vascular communication; though even in these cases, the impression is extended more through the sympathies which bind together the extreme vessels, and the nervous communication of the parts (§ 526, a). Comparatively little seems to be due to the imputed derivation of blood. Thence, upon our principles, appears the reason why, according to Dr. Wardrop, "in diseases of the head, as well as in diseases of the eye, more particularly those affecting the internal parts of the globe, leeches applied to the frontal vessels give much more relief than is obtained by abstracting an equal quantity of blood from the temporal vessels by leeches applied to the temples." He also states that a like advantage will be obtained, in cerebral affections, by applying leeches to the lining membrane of the nose, or behind the ears. He thinks the effect greater than when applied to other parts.-Note DD p. 1132.

923, c. In all the cases, however, the effects appear to be mainly produced through the agencies which I have stated. Whenever I have applied leeches to the nasal septum abdominal disease attended the

^{*} Notes Ff p. 1135, Gg p. 1138, II p. 1139.

head-affections. The leeches have sometimes relieved the headache, when general bloodletting, cathartics, &c., had failed, while the gastric derangement had also persisted. But, simultaneously with the relief of the head the secretions from the bowels improved, the tongue cleared up, and the stomach and other abdominal organs were relieved. It would appear, therefore, that, as in the case of leeches to the verge of the anus under similar circumstances, the specific impression of leeching the nasal septum is propagated continuously and by reflex nervous action, by the instrumentality of the mucous membrane, to the viscera of the abdomen, and that the head is as well relieved by thus removing this source of morbid sympathies, as by the

more direct impression (§ 524 a, no. 2).—Note Up. 1126.

923, d. Hence it follows, as shown also by experience, that leeching will generally exert the greatest effect upon diseased organs when applied to some part with which the organ affected may have strong physiological relations (§ 129, 139, 140). For this reason, and for the advantage of continuous sympathy, leeches should be applied to the anus in muco-intestinal inflammation; but, to the cutaneous region when inflammation affects the peritoneal coat of the intestines or abdomen. There are greater natural sympathies between the skin and peritoneum than between the mucous membrane and the peritoneal. Where no remarkable relations subsist among organs the leeches should then be applied near the vicinity of the part affected, as when the pleura, or parenchyma of the lungs, or the joints, are the seats of inflammation. In such cases we obtain the advantage of local reflex actions as in the case of blisters, &c. (§ 497, 891 $\frac{1}{2}$ g-k, 893 a, c, f).

924. And now a word more as to the doctrine of Revulsion, or that, for example, which supposes that when leeches are applied to the feet for the relief of cerebral disease the effect depends upon the diversion of blood from the head toward the feet. And so of cathartics in their action upon the intestinal canal, and of blisters by diverting the blood to the skin, &c. (§ 893, n). Nothing can be more unfounded. But, do not leeches, when applied to the feet, exert a greater influence upon diseased conditions of the uterus than upon any other part ? They probably do; and it is a forcible illustration of remote sympathy, and coincident with that which is supplied by the suspension of the catamenia from exposure of the soles of the feet to cold, or by the production of catarrh when a current of cold air from a key-hole impinges upon the neck. Just so, if the female now plunge her feet into warm water, or apply leeches upon or near the soles of the feet, the catamenia may be restored. So, too, in relation to cerebral affections, who does not know that a natural sympathy subsists between the feet and the head? "In affections of the head and thoracic viscera," says Dr. Wardrop, "I have, in many instances, recommended patients to apply leeches on the head, chest, and on the feet, alternately; and almost universally, I may venture to say, a decided preference has been given to the feet."* The philosophy is the same in all the cases, and revulsion is reflex nervous action. Dr. Wardrop, however, had already preferred the application of leeches to the nasal septum, or to the temples, in affections of the head; though his observations as to the feet are also founded on sound experience. As to leeching in amenorrhœa, the remedy has the greatest effect when applied to the perinæum, or to the upper part of the thighs .- NOTE DD. "It is well illustrated by Brown-Séquard's exper, of producing epileptiform convulsions as in § 1037 a

925, a. What has been now said of disease supposes that leeches are applied under circumstances favorable to their effect. Before this condition can happen, however, in numerous cases where leeching may be ultimately useful, it may be necessary to make a strong impression by general bloodletting; and if two or more general bloodlettings be likely to be wanted, the leeching should be delayed (§ 893 g-i, p,

927), or until the exciting nervous action is subdued.

925, b. Nevertheless, if the chance of leeching alone be taken in these cases, the number of leeches should be very large for adults, that the benefits of general bloodletting may be more or less obtained, through a rapid and copious abstraction of blood. This practice will often succeed in infancy when it will fail at more advanced age; since the loss of blood is more sensibly felt in the former case, and less is required, and the requisite amount is therefore, also, more rapidly abstracted, notwithstanding, too, the ratio of the loss, in proportion to age and size, may be actually greater than in adults. Thus, too, the advantages of general bloodletting are more or less obtained. In similar cases cupping is also more beneficial to children than to adults (§ 576, e).

925, c. Leeching, or cupping, however, should never supersede general bloodletting in the cerebral inflammations and congestions of infants. In the phlegmatic temperament of adults leeching may answer where it would be inefficient in other temperaments (§ 600). But I speak of these cases rather to illustrate a principle than to raise any doubt as to the propriety of general bloodletting in the grave vis-

ceral inflammations of any age after infancy (§ 1009).

926. Experience teaches that frequent and small abstractions of blood by means of leeches is often more beneficial in chronic inflammations than a greater quantity at more distant intervals. This corresponds with what I have said of the vital influences of leeching, and of the effect of habit in maintaining disease (§ 549, 560). In these cases, the impression, being frequently repeated, maintains the salutary change which may be produced more perfectly against the morbid influence of habit than greater losses of blood at distant intervals (§ 514 g, 535, 540, 542, 548, 549, 557). We see the same principle more frequently exemplified in the effect of blisters upon chronic inflammation; where it is better to apply them frequently, and to a moderate extent, than more rarely and over a larger surface. The philosophy is the same, also, in respect to the relative effects of a large dose of calomel, and that dose divided into four. Analogies likewise subsint between the salutary effects of copious leeching, extensive vesication, and a large dose of calomel, in acute inflammations (§ 559, 893 h). And so of numerous other agents. A common philosophy obtains in all the cases, and each example illustrates and confirms the principles on which all other agents operate. And I may here carry the same examples to illustrate the philosophy of the operation of general bloodletting, and the peculiarities which appertain to that mode of abstracting blood; since, as will appear, its influence on the organic properties and functions is more immediately, and may be more profoundly, felt than leeching or other agents; and, being antiphlogistic, it is therefore better adapted to high grades of active inflammation and fever (§ 557). The philosophy of the whole is alone re solvable through reflex actions of the nervous system (\$893 h)

927, a. Notwithstanding, therefore, the last proposition in respect to leeching, it often happens that the force of diseased habit is so great as to demand a more decisive and more frequent resort to leeching. It is even not unfrequent that the force of morbid habit attendant on chronic inflammations requires the previous abstraction of blood from a vein, and perhaps repeatedly and largely; not only with a view to the special physiological influences of general bloodletting, but that a large diminution of the general volume of blood may be suddenly effected (§ 925, a). The utility and necessity of this practice are frequently seen in the treatment of those chronic inflammations of the mucous tissue of the stomach which follow long-protracted indigestion, and especially if the liver also have become invaded by the same condition of disease. The advantages of general bloodletting in these cases relate as much to the general condition of the system over which a morbific influence has been established as to the seat of inflamma-The general modification exerts a reacting effect upon the part inflamed, and adds to the obstinacy of the diseased habit of the part, and leeching will not reach these influences (§ 143 c, 847 g). Here it is, particularly, that we witness corresponding, and even more successful, efforts of nature at relief in the torrents of blood that are effused from either the mucous tissue of the stomach or of the lungs;

especially the former (§ 890, e).

927, b. Again, in certain mild, though obstinate cases of purely local inflammations, and before the constitution is brought under the influence of the morbid action; or, in cases where exciting reflex nervous actions have been subdued by general bloodletting, local bleeding by leeches is pre-eminently useful. In either of these cases, general bloodletting continued to a large extent, by the suddenness and violence of its impression, may so disturb the system at large that the inflammation may be kept up by influences produced by this artificial derangement of the whole body (§ 889 m, 889 mm). But here there is no countervailing action against the effect of leeching; and while the small vessels engaged in the inflammatory process refuse to give way if the disease have been of short duration, there is no danger of establishing any injurious influences upon the general capillary system. This, however, will take place, more or less, when leeching exceeds that degree which is necessary to determine a change in the part inflamed. It may even follow from very copious leeching in severe chronic inflammations, where morbid action is rendered obstinate by the influence of habit, before the diseased process yields. In the former case, the system is injured partly by the influences determined by the excessive change induced in the instruments of morbid action, and, in part, by the general influence from an unnecessary loss of blood. In the latter case, the bad effects appear to be mainly incident upon the loss of blood in its general relation to the system at large. In these cases, therefore, it is important to graduate the extent of leeching by the exigencies and the peculiarities of each individual case; and it is especially important with infants, upon whom leeching produces not only its peculiar effects very powerfully, but, also, more than in after life, the effects that appertain more strictly to general bloodletting. Such is the obstinacy of the depressing change in the instruments of disease, as liable to arise from leeching in infancy, when this remedy has been carried far beyond any useful degree in inflammations of the nature now under consideration and its influence upon the whole extent of the circulatory organs is maintained with such violence, that, having also superadded to it the general effect from excessive loss of blood, it may be impossible to counteract its destructive tendency (§ 514 g, 516 d, no. 6). It is not alone the effect that arises from an excess of general bloodletting with which we now contend, but a greater, perhaps, in that pernicious chango which has been induced in the extreme vessels to which the leeches had been applied, and which, indeed, has been more or less propagated by reflex nervous action over the system (921).

928. From what has now been said, the reason is apparent why cautious leeching may be sometimes a means of relief in those inflammations that are now and then induced by a misapplied or an excessive loss of blood. In these rare affections, the triumph of art is beautifully illustrated when accurately guided by the light of science. The effect should be limited, if possible, to local nervous centers. They are cases, too, in which the distinction between general bloodletting and leeching is forcibly shown, since the former has caused the disease and the latter cures it (§ 1024 a, f, Dr. M. Hall).—See Note p. 708.

2. GENERAL BLOODLETTING.

929. In general bloodletting the effects are varied from those of leeching, and in a way, as we have already seen, of practical importance (§ 927, 928). Its influences may be considered under five

general aspects, and successively as in leeching:

930. 1st. The earliest impression is made simultaneously upon the organic properties of the large and small vessels throughout the body, since the loss of blood is now immediately coextensive with the whole circulating mass, is suddenly withdrawn, and in a comparatively large quantity. Here, therefore, as of the local vessels in leeching, a change is instituted in the vital state of the blood-vessels throughout the body (§ 526 a, 915, 921, 944 c).

931, a. 2d. The foregoing impression suddenly rouses the arterial system to a greater, but very modified action, by which the vessels, especially the extreme and capillary, are brought into a state of contraction, and far beyond any diminution of their contents that may arise from the quantity of blood removed from the body (§ 916).

931, b. The contraction thus instituted is vastly greater in the small than in the large vessels, mainly because of the greater endowment of the former with irritability and mobility (§ 188, 205, 482, 944 c).

932. 3d. Owing, also, to the same causes through which the extreme vessels feel the loss of blood more sensibly than the larger ones, powerful reflex nervous actions are determined upon the former by the changes which take place in the larger series of vessels ($\frac{5}{222} - 233\frac{4}{3}, \frac{409}{411}, \frac{475\frac{1}{2}}{500}, \frac{500}{m}, \frac{687\frac{1}{2}}{688}, \frac{694\frac{3}{4}}{3}, \frac{826}{cc}, \frac{920}{300}$).

933. 4th. As soon as the foregoing change begins in the vessels, it throws a reflex nervous action over the heart. There is, as yet, so little diminution of the general volume of blood, that the earliest influences upon the action of the heart must be due, entirely, to this reflex nervous impression (§ 919, 500 m, 826 cc, 829).

934. 5th. As the heart becomes influenced, it excites a powerful reflex influence that falls upon the extreme and capillary vessels; between which and the heart there exist very strong vital and sympa-

thetic relations (§ 385, 526 a, 920, 1039).

Here, therefore, as in leeching (§ 920), the contraction, and other changes, which take place in the small vessels, grow out of a double influence; namely, that which is exerted by the direct impression from loss of blood, and that which is reflected upon them by the changes that arise in the heart and larger vessels. And so, as in leeching, reflex nervous action between the heart and blood-vessels passes and repasses, and increases in an increasing ratio as the blood flows from the arm, till its prostrating effect reaches the point of syncope. In leeching, however, the sympathies between the heart and blood-vessels are not as reciprocal as in general bloodletting; but a greater influence is often propagated in leeching by the small vessels upon the centre of circulation (§ 921, and references in § 932).*

935, a. That the failure of the heart's action does not arise, as commonly supposed, from a mechanical diminution of the volume of blood is shown by the frequent occurrence of syncope from the loss of two or three ounces; nor does it depend, in the least, upon withdrawing the stimulus of blood from the heart. On the contrary, as it respects both hypotheses, the blood is actually accumulated about the heart in consequence of the contraction of the capillary vessels; and this accumulation, from the beginning, is a cause of the failure of the heart's action, and is at its greatest extent when syncope takes place

(§ 936, and references in § 932).

935, b. It is also equally true that the general contraction of the small vessels, in all the modes of abstracting blood, is not referable to either of the foregoing causes; and for the reasons, in part, that the contraction far surpasses any diminution of the general volume of blood, that the phenomenon is always attendant on syncope arising from mental causes, and that the contraction, if proceeding from elasticity or from any other cause than one of a vital nature, could never determine the powerful reflex nervous actions which it exerts upon

the heart (§ 916, 917, 932, 937).

935, c. In like manner, the diminution of the volume of blood in inflamed parts is only a remote effect of lessening the quantity of the circulating mass. The blood is not only temporarily, but permanently expelled from the injected vessels. This shows that its expulsion is effected by a vital change in the condition of the vessels; otherwise, they would not contract in a ratio exceeding that of the corresponding vessels of other parts, nor would their contraction be permanent. Vessels that are enlarged in inflammation to many times their natural diameter are often reduced to nearly their natural volume while the

operation of bloodletting is in progress (§ 910, 977, 1056).

Various circumstantial facts might be adduced to show the vital nature of the contraction which attends the capillary vessels. The following are relative to idiosyncrasy; and the principle which I have set forth is an evidence of the accuracy of the reporter's interpretation of the phenomena, throughout. Thus: Dr. Paige, "of large experience and great respectability," states, in the November number (1845) of the "New York Journal of Medicine," that, on bleeding "a woman about forty years of age, and after having drawn a very few ounces, and while the blood was still flowing from the vein, she was taken with very severe pain all over the external parts of the system, and extending to the most remote extremities. I suffered the blood to flow, however, but the pain increased instead of diminish-

^{*} This sensitiveness of the heart and arteries to the nervous influence excited by loss of blood corresponds exactly with that from all things else, as shown in § 500 m.

ing." "Several years afterward I met with exactly the same symptoms on bleeding a young man in case of an ardent fever; but, having thought much of the first case above mentioned, I had come to the conclusion, in my own mind, that the pain depended on the spasmodic contraction of the small vessels of the surface and extremities as they became emptied of their blood. I, in this case, immediately administered a free dose of some diffusible stimulus (I think, of ammonia), and the pain subsided very soon, so that I was able to take as much blood as I wished" (§ 399, and references in § 932).

935, d. Again, bloodletting being, in popular language, a debilitating remedy, its rapidly salutary effects contradict the prevailing by pothesis that inflammation and venous congestion are constituted by debility of the vessels, and stagnation of blood. Had this doctrine any foundation, the capillaries in inflammation, and the veins in congestion, would immediately become more injected with blood, and those diseases should be exasperated by what is known to be their most efficient remedy. It also fully contradicts "coagulation."

The effects of bloodletting, therefore, prove that the pathological cause of inflammation and venous congestion consists not only of an increased energy of the organic properties, but that these properties are also modified in kind; while the rapid subsidence of the foregoing affection, under the influence of loss of blood, proves, abundantly, that the whole process advances upon vital principles. The loss of blood so impresses the diseased properties, that their pathological state is changed on the instant (§ 137 d, 143, 150-152), and they are brought to obey their natural recuperative law so immediately, that the vessels of an inflamed eye contract and disappear while the blood is yet flowing from the arm. And so of all other parts that are concealed from observation (§ $476\frac{1}{2}h$, 478, 479, 503-506, 516d, no. 6, 750h, 751, 817).

935, c. The extent and durability of this change will depend upon a variety of circumstances; such, for example, as relate to constitution, the nature of the remote causes, and whether, also, the impression have resulted purely from the loss of blood, or, in part, from mental emotions, or from gastric irritation; and it will be often influenced by the manner in which the blood may be abstracted, whether from a large or a small orifice, or whether the operation be suspended for a minute and then resumed. Each of these circumstances, also, discloses the nature of the principles upon which loss of blood produces its effects, especially the agency of the nervous influence.

936, a. When general bloodletting is practiced in health the action of the heart begins to fail as soon as the vessels begin to contract; but it is the tendency of inflammation to delay or prevent the vascular changes under an equal loss of blood, while, on the other hand, those changes are often promoted by venous congestion, or by numerous

adventitious influences, either mental or physical.

936, b. Again, it frequently happens, after the action of the heart is more or less subdued by loss of blood, that it speedily recovers its force on account of the removal of the prostrating influence of some morbid condition, or of nausea, or of mental disturbance, which removal may be suddenly effected even in the case of some depressing form of disease, and perhaps as soon as the blood begins to flow from the vein (§ 938, b), just as the nervous power may be modified.

937, a. Since the influences of general bloodletting are exerted, from

the beginning, simultaneously upon the whole capillary system (§ 930), the amount and rapidity of the primary change will depend on the suddenness with which the blood is abstracted; and whenever loss of blood produces a great and sudden contraction of the whole capillary system, however small the quantity, syncope will approach (§ 935).

937, b. And so, also, it was found by Le Gallois and Philip, in their direct experiments upon the brain and spinal cord, that the extent of the nervous influence upon the heart, blood-vessels, and alimentary canal, depended, always, on the suddenness of the impression on the nervous centres, and that when most sudden and violent it was capable of extinguishing at once the functions of life (§ 478, 479, 510, 511).

937, c. Now, as will have fully appeared, the sympathetic changes which take place in the heart and blood-vessels, in general bloodletting, depend upon the operation of the nervous power; just as, in the direct experiments by Le Gallois and Philip, the organic functions were variously affected according to the nature of the influences which were inflicted upon the nervous centres. It is, therefore, already apparent that the effects of bloodletting upon disease will often depend much upon the rapidity with which the blood is abstracted. And this important practical consideration points out another difference between general bloodletting and leeching, and why, in the language of Mr. Travers, "syncope is in proportion to the suddenness, rather than the quantity of the hemorrhage." Hence it is that syncope follows from the loss of a smaller quantity of blood when drawn from a large than from a small orifice, or from both arms than when from one (§ 1056); from the more sudden excitement of reflex nervous action.

937, d. It is also another important practical, as well as philosophical, consideration, that if the subject be in an erect posture, syncope will follow sooner than in the horizontal, from the greater inability of the heart in the former case to transmit the blood to the brain; and this circumstance, as will appear, should govern us as to

the position of the patient.

938, a. Again, the ratio, in which the various influences that arise from general bloodletting will succeed each other in disease, will also depend on the existing condition of the organic states, especially of the heart and blood-vessels (§ 143, 149, 150, 152). It often happens that an increased and uniform susceptibility pervades the whole sanguiferous system; and when this peculiar state exists, the abstraction of a very small quantity of blood may instantly determine a paroxysm of syncope (§ 526 a, 961), the nervous power then acting intensely.*

938, b. This proposition, like all the others which are made without qualification, supposes the influences to depend upon the absolute loss of blood, and not to be affected by adventitious causes, such as emotions of the mind, intestinal irritation, &c. When these accidental and transient causes institute their reflex and prostrating nervous actions, they should be carefully noted; since it is commonly important that a certain amount of blood should be abstracted to produce the requisite impression upon disease. In such cases, therefore, it is commonly necessary to go on with the operation, sooner or later, but generally early, after the patient has revived. The nervous influences of the adventitious causes generally make but little or no impression upon disease; and the loss of too little blood often adds violence to inflammation and fever by imparting greater energy to the action of

the heart, or by relieving the general circulation when it may be embarrassed by some local venous congestion (§ 988).

3. CUPPING.

939, a. Cupping differs in some of its effects from leeching and general bloodletting. Its influences are of an intermediate nature, but are most allied to the latter. It never makes the profound impression upon the vital condition of the parts to which it is applied that is exerted by leeching, and its influences upon the system at large are also less, under equal circumstances. Cupping, indeed, often fails of relief where leeching is speedily efficient. In a general sense, six ounces of blood taken by leeching is probably equal in its curative effects to nearly twice that quantity abstracted by cupping.

939, b. In cupping, the blood is abstracted from the larger series of capillary vessels, whose office is probably but little more than to supply the smaller series, in which the organic properties are most strongly pronounced (§ 384, &c.); nor is that action instituted, by cupping, in those vessels from which the blood is taken, that obtains so profoundly in leeching, and upon which no little of the general and local effects depend, especially the peculiarity of the reflex nervous action.

939, c. The distinction is also explained by the persistence with which the blood continues to be discharged long after the leeches have performed their office, although smaller and fewer vessels are divided than in cupping, and these few torn, while in cupping the blood ceases to escape as soon as the cupping-glasses are removed. All of which is absolute proof that a remarkable change is instituted in the vital condition of the capillary vessels, by leeching, and that the prolonged effusion of blood is in no respect of a mechanical nature, but wholly due to a vital action which is artificially set up in the vessels, and which is not at all instituted by cupping.

939, d. It is evident, therefore, from principle as well as experience, that cupping-glasses should not be applied, as is often done, to promote the bleeding of leech-bites. It embarrasses the specific action instituted by the leeches. A mechanical is substituted for a natural process; while, also, as in cupping, the abstraction of blood is so rapid

that its effects become more like those of venesection.

939, e. Cupping approximates general bloodletting not only in the rapidity with which the blood is abstracted, but in which it determines reflex nervous actions upon the whole circulatory system, and in the quantity of blood which is required for its physiological and therapeutical effects. It is more remotely allied to leeching in the change which is locally induced, though this change is not of a specific character, but consists of a more simple vital contraction of the small vessels that propagates comparatively little impression upon other parts of the circulatory system. When the impression becomes general, it is then mostly due, as in venesection, to the removal of a quantity of blood adequate to a universal influence.

939, f. It becomes more and more apparent, therefore, that general bloodletting, cupping, and leeching are in some respects distinct remedies, and that cupping is the least useful and rarely required. The difference between them lies in a difference in the operation of the principles which are common to the several modes. Some of these differences appertain to the cerebro-spinal system, which is far more

concerned in the phenomena of general blood-letting than in the usual effects of leeching, which is apt to engage mostly local nervous centres. The effects of general blood-letting may be obtained in an inferior degree by cupping, through more inconsiderable degrees of the same influences, as, also, in a still lesser degree by applying cupping-glasses in the operation of leeching. The difference in leeching is owing, in part, to a more profound impression upon the sympathetic nerve, though the other methods transmit their influences through this nerve (§ 921, 922).

Of the Nervous Power in its Relation to the Effects of Loss of Blood.

940. This very important element in the phenomena which arise from loss of blood must be amply reviewed. It is the nervous power to which are owing all the remarkable results that are in active progress after the beginning of the constitutional effects of blood-letting. The operation of this power commences at the earliest contraction of the small vessels, and increases in the ratio of that contraction. It is the same power that exerts so vast a range of influences in directing the effects of all other remedial, as well as morbific agents, and whose characteristics have been already extensively considered. The same philosophy, too, is here applicable as in all other cases in which the nervous power is instrumental in organic actions, or in modifying, or in propagating disease (§ 222–234, 450–530).

941. The development of the nervous power from loss of blood is owing to the vital impressions that lead to the contraction of the small vessels. The influence upon the nervous centres is thus of two kinds—that transmitted by vascular contractions in other parts, and that from the contraction of their own vessels; being, in the latter case, analogous to what we have seen to arise from direct experiments (§ 476–494), from the operation of the passions, and from the reflected action of remedial and morbific agents (§ 227, 500, 944 c, 1039, 1040, 1056).

942, a. Now, therefore, in view of the extensive premises before us, loss of blood, both by its profound influence upon the small vessels of the nervous centres, and by effects transmitted there by vascular contractions in other parts, develops the nervous power in a peculiar manner and in unusual intensity (§ 227, 232). This influence of this power, reflected abroad, increases that contraction of the general capillary system which is at first instituted, in all parts, in general blood-letting, by the direct effect of loss of blood upon the organic properties of the whole system of blood-vessels (§ 930, 931, 944 c).—Note Q p. 1122.

942, b. In leeching, the local impression generates an alterative reflex nervous action upon susceptible parts through centres of the ganglionic nerve, and when strongly made is transmitted to the brain and spinal cord and occasions a general reflex nervous influence (§ 113, 224, 893 a, c). The general contraction of the vessels is thus more and more accelerated as the loss of blood goes on, the nervous power is more and more excited, and prostrates the action of the heart, and this in an increasing ratio as syncope approaches—Note Do p. 1132.

942, c. There is not, therefore, as has been universally supposed, a withdrawment of the nervous influence from the heart during a paroxysm of syncope; but, on the contrary, an increased determination of that power upon the organs of circulation, which, indeed, is then at its acme (\S 475 $\frac{1}{2}$, 476 $\frac{1}{2}$, h, 479, 481 c, 487 g, 500 m, 509, 828 b, 951 c, d). 943, a. Again, it has been shown by Le Gallois, Philip, and others.

that the stomach and intestines are readily and powerfully influenced by impressions made upon the central parts of the nervous system (§ 491); as they also are, like the heart, by mental emotions. As soon, therefore, as the nervous centres are influenced by loss of blood the nervous influence is felt as well by the stomach as by the heart and blood-vessels. This gastric irritation is propagated back to the brain and spinal cord, and increases their depressing influence on all the organs. This is especially manifest immediately before the occurrence of syncope, which it contributes to hasten. Hence, also, the frequent nausea and eructations, and the intestinal evacuations, which supervene upon the impressions made on the brain and spinal cord, or as syncope approaches (\S 902, g). It is for this reason that cathactics often operate during the progress of general bloodletting, when they had failed antecedently, and where no intestinal inflammation had existed to interfere with their effects. And this consideration, by-theway, is important to the practitioner when he is deliberating whether oloodletting should precede the exhibition of a cathartic or an emetic.

943, b. But, it is also true that the intestinal disturbance is often owing to the effect of nervous influence excited by some emotion of the mind (§ 892\(^3\)4, b); when its reaction upon the nervous centres may be equally as great as when the disturbance results from the loss of blood, but has little or no effect upon disease, and may embarrass the practitioner, and sacrifice the patient to an imperfect application of the remedy (§ 938). Nevertheless, it is important to say that exceptions sometimes occur; and when such demonstrations are made, they yield the most convincing proof of my doctrine of the agency of the nervous power in the physiological results of bloodletting, and its alterative influence upon disease by whatever cause the influence may be excited. Thus: "A patient," says Dr. Armstrong, "was so alarmed at the preparation for bleeding, that syncope occurred, and completely stopped an inflammation of the pleura." Again, "cheer up the patient, and he is always sure to do well" (§ 227-230, 232, 1067).

944, a. When syncope arises from the depressing emotions, or from other causes whose primary impression is upon the brain, the action of the heart is directly prostrated through the nervous influence, and by a reflex action instituted by the stomach; while a certain depressing effect is exerted by the nervous power upon the extreme and capillary blood-vessels, and an influence from this change is propagated by reflex action to the heart. The succession of changes then, as respects the heart and blood-vessels, begins more on the side of the heart than when they are determined by loss of blood; the contraction of the capillary vessels being also more consequent on the failure of the heart's action than on the alterative influence of the nervous power. We must also explain, in the foregoing manner, the syncope which follows blows upon the stomach, the crush of limbs, surgical operations, &c.; and when death is suddenly produced by any of these causes, it is owing either to a sudden extinction of the cerebrospinal functions, or to a powerful determination of the nervous influence upon the heart, &c., by which the action of that organ is arrested (§ 230, 480, &c., 510, 511). The same is true of the prostrating effects of nausea, and many other accidental influences which spring up during the operation of bloodletting.—See § 476½ h, 479, 902 g. 944, b. Since, therefore, in the case of bloodletting, its influences are profound, not only on the instruments of disease, but upon the whole capillary system, and the failure of the heart's action is greatly due to this deep impression on their vital constitution, while in the case of the accidental causes the effect consists mostly in a direct depression of the heart's action, and a consequent failure of supply to the capillary vessels, without essentially affecting their vital states, it is obvious that we may not depend on syncope as a test of the influences of loss of blood (§ 959).

944, c. The contraction of the blood-vessels as arising from loss of blood is an incidental result of a profound impression upon the vires vitx, which is essentially the cause of the development and modification of the nervous influence. The contraction, therefore, is only an evidence that such profound impression has been made, just as in other exemplifications by cathartics and emetics (§ 889 f, 902 g). The vascular contraction occasioned by fear, &c., produces no such effects (§ 892 $\frac{3}{4}$ b, 900, 902, 954 d, 961 e, 966, 986 b, p. 837, § 1057 $\frac{1}{2}$, p. 827, p. 920 Note).

944, d. Syncope is often consummated by removing the ligature. In this case the action of the heart had been enfeebled almost to an accession of the paroxysm, and the additional quantity of blood suddenly thrown upon the heart, so far from rousing the organ, overpowers its action. It is in this way, in part, when the heart has been gradually prostrated during the access of congestive fever, that a sudden development of the attack sometimes produces syncope. Something, however, is evidently owing, in this case, to the reflex nervous influence of the extreme vessels upon the heart, but probably more to the sudden determination of blood from the circumference at the access of the cold stage.

945. If syncope be obstinate, the means of relief will be such as operate through the medium of the nervous centres, and should be of such a nature as will subdue the depressing character of the nervous influence, and render it stimulant to the heart and blood-vessels. Pungent vapors to the nose, cold air, cold water dashed upon the surface, stimulants introduced into the stomach and intestine, and exciting means of a corresponding kind, as well as perfect rest, will

therefore be the proper remedies (§ 481, e, $891\frac{1}{2}$ k).

In the Medical and Physiological Commentaries, vol. i., p. 178 (1840), I proposed, in cases of obstinate and alarming syncope, the operation of acupuncturation of the heart; deriving my suggestion from Marshall's experiments upon frogs, which were revived by that process when apparently dead from carbonic acid. Very lately (1843), I see in the Annali Universali di Medicina, that Dr. A. Carraro has successfully repeated these experiments, and makes the same application to the human subject as had been done by myself. The whole

is also commonly supposed to be original with Carraro.

When syncope supervenes, if the subject be laid in a horizontal posture animation returns, and it may be again suspended by reversing the position. These phenomena depend upon causes now essentially modified. "No man ever saw the sensorial functions continue a single minute after the heart had ceased to move. When the body is horizontal, the heart circulates the blood more easily, than when any part, and especially so large a part as the head, is elevated." If syncope return when the head is again elevated, it will depend on a more simple cause than what originally produced it. It will now arise from a permanently enfeebled state of the heart, and "its ina-

bility to continue the circulation, and thus to supply the brain and an other parts with blood;" and such is always the last in the series of causes in a paroxysm of syncope. In the first instance the action of the heart is prostrated through the nervous influence of the brain and spinal cord; in the second, the functions of the brain are impaired or suspended through the enfeebled action of the heart ($\sqrt[6]{476\frac{1}{3}}f$).

946, a. Many examples may be found in my Essay on the Philosophy of the Operation of Loss of Blood, which show the great alterative nature of the nervous power as developed by bloodletting. Let one suffice at present. Thus: "A patient," says Dr. Armstrong, "having lost only an ounce of blood, from the shock of the operation syncope came on, and effectually removed an acute inflammation of the brain" (\S 476 $\frac{1}{2}$ h, 478, 479, 494, 509–511, 827 d, 828 b, c, 943).

946, b. Examples of the foregoing nature admit but one interpre-They are clear illustrations of the peculiar properties and laws by which organic beings are governed. They are simple elements of the whole philosophy of which I have spoken, as it respects the specific nature of the properties and actions of life, of their mutability, and of the tremendous influence which the nervous power is capable of exerting upon them. It is the same, also, when life is instantly extinguished by a drop of hydrocyanic acid, or of the alcoholic solution of the extract of nux vomica, applied to the tongue, or by a blow on the epigastrium, by surgical operations, &c., through reflex actions of that power ($\sqrt{222}, 455 d, 476\frac{1}{2} h, 479, 500 c, 509,828$).

947. The philosophy of syncope, as expressed by M. Piorry, has been the philosophy of no small part of the medical world; while all the antecedent influences of bloodletting have been more universally referred to the mechanical diminution of the circulating fluid, and syn-

cope construed upon this doctrine.

"Syncope," says the eminent Piorry, "whatever may be its cause, consists in a suspension or diminution of cerebral action. If it take place spontaneously and from a moral cause, it is the action of the encephalon that is suspended; it is the influence of this organ upon the heart which is diminished."

We have seen, however, in the ordinary state of the body, that the nervous system has little other influence upon the organic functions than that of contributing to their fundamental action; these functions being all carried on by the organic properties, which are maintained in operation by stimuli peculiar to each, but mostly by the blood. The nervous power becomes a stimulant, or depressant, or modifying cause, to the organic and animal functions only as developed by those stimuli or by other physical or moral causes (§ 177-191, 223, 226, 227, 232, 478, &c.). It is also fully demonstrated that the entire removal of the brain and spinal cord does not affect the action of the heart, if respiration be artificially maintained (§ 477, 479, 481 h), when the muscular motion of the heart is excited by reflex action of the ganglionic system ($\sqrt[6]{475\frac{1}{2}}$). When we consider, also, how powerfully the heart may be influenced by slight mechanical or other agents applied to the brain, or spinal cord (§ 480, &c.), even when the cerebral circulation is destroyed, and the whole inferior portion of the organ removed, we shall better understand, in this way, how loss of blood. odors, offensive sights, and mental causes, produce syncope, than by supposing that it is through their direct suspension of the cerebral

Violent passions have, doubtless, the effect of extinguishing, at once, the powers and functions of the brain; but then the action of the heart ceases at once, and is clearly owing to the sudden lesion of the brain, while in syncope the action of the heart is only diminished. Nevertheless, even in the former case, a pernicious nervous influence is suddenly determined upon the whole circulatory system (§ 479, 509, 510). Again, it is only the depressing emotions, like fear, grief, disgust, and such causes as in any degree exert a sedative influence on the circulation, that are known to produce undoubted syncope, while those like joy and anger, which always excite the action of the heart, alone extinguish life instantaneously. One affection, too, is common, while the other is rare; and when the latter takes place it is probable that there exists an apoplectic predisposition. In one case the action of the heart is suddenly depressed; in the other it is powerfully excited. Doubtless, too, in the latter instance the violent impulse of the blood upon the brain contributes, per se, to the sudden subversion of the cerebral powers. While, therefore, in syncope from fear and grief the blood is, at the onset, diverted from the head; in sudden death from joy or anger a preternatural quantity is determined upon the brain (§ 227, $476\frac{1}{2}h$, 500 m, 826 cc).

948. It appears, therefore, that the various changes which take place in the action of the heart, when they arise from loss of blood, are chiefly dependent on reflex nervous influence, or remote sympathy, and that this influence is greatest when syncope ensues (§ 481, h). Nor is there at any stage of that complex series of changes, from the first impression that follows the loss of blood to their end in syncope, a deficiency, but a redundancy, of blood at the centre of circulation; and, if death ensue, the vital fluid is always found accumulated in the

cavities of the heart (§ 1039).

949. Summarily, also, we have now seen that it is the effect of loss of blood, per se, to so modify the vital states of the capillary blood-vessels as to result in their contraction, and that when this contraction begins in the vessels as the effect of the loss, it excites the nervous influence in proportion to the extent and suddenness of the impression; that this influence is then propagated abroad, and increases the contraction of the capillaries at large; that this effect of the nervous influence is reflected back upon the nervous centres, by which the nervous influence is still farther excited; that circles of reflex actions become thus established; that the nervous influence is now, also, exerted with a depressing effect upon the heart, and intestinal canal, and that this effect is reverberated upon the brain and spinal cord, by which the intensity of the nervous influence is farther increased; that the reflex nervous actions, and the multiplying causes of nervous influence, become, therefore, exceedingly complex, and increase in their ratio till the heart is prostrated by that influence and by the central determination of bloud, when syncope takes place as an immediate consequence (§ $476\frac{1}{2}$ h, 481 h, 500 m, 944 c).

But, we have also seen, that if too little blood be taken, in certain conditions of disease, results of an opposite nature to the foregoing, and an aggravation of disease, may ensue, though they will be brought about through the same physiological principles (§ 965, 983-989). Natural laws are at the foundation (§ 901, 904 a, bb).

And now I say, if the foregoing results of loss of blood be com-

pared with the effects of other remedial or morbific agents, it will be found that a close analogy and harmony of laws distinguish their modus operandi. And such is always the simplicity of nature in her fun-

damental institutions (§ 137 e, 150-152).

950. From what has been now seen of the profound influences of bloodletting upon the nervous centres, especially when syncope approaches, we readily account for those inflammations, and that far overrated irritation of modern physicians, which occasionally supervene on the loss of blood (§ 1020-1023); sometimes, though rarely, from an excess of the remedy, but more frequently from its deficiency, and still more so from its frequent application in small quantities where a greater loss is demanded. If the loss be excessive, or blood-letting not appropriate to the case, it gives rise to a morbific reflection of the nervous power upon the capillary blood-vessels. When the loss is small and frequently repeated, an irritable state of the whole vascular system is thus established, which may not only increase the inflammation which the remedy was intended to subdue, but may become the foundation of disease in other parts (§ $476\frac{1}{2}h$, 479, 500m, 965h, 982-1001, 1005e, 1024; also, Kriemer's Experiments, § 485).

In all these cases the whole system of capillary blood-vessels has a large share in the primary impression; but a peculiar influence is determined upon them by the violence inflicted on the extreme capillaries of the brain. Inflammation, therefore, may be lighted up, as a consesequence, either in the brain or some other part, but especially the brain (\$ 230, 231). Hence, also, the general vascular excitement, and that delirium, coma, stertorous breathing, and those convulsions, retchings, and involuntary intestinal evacuations; some of which so frequently follow excessive loss of blood. Although blood-letting, therefore, be a remedy for inflammation, the excessive use of it, as will be farther shown, may induce that affection; and even then the cautious abstraction of blood by leeches still proves, by its curative influence, as reported by some, the nature of the affection, and the sanative power of the remedy when well directed (§ 901, 997, 1024 a, 1057).*—Note Q.

951, a. Let us now regard the foregoing morbific effect of loss of blood (§ 950) in connection with two examples, one of coincident, the other of an opposite, nature, to show the effect of the nervous power upon the capillary vessels of all parts, as illustrative of this agency in the operation of blood-letting, as well as of all other remedies. The first example is the greatest glance that has been made toward the practical philosophy of the nervous system as expounded in this work, and as first developed in the Med. and Physiolog. Comm.—Thus:

"It is certain," says Müller, "that nervous influence is the principal cause of the accumulation of blood in the capillaries of certain parts during the state of vital turgescence." "In the instantaneous injection of the cheeks with blood in the act of blushing, and of the whole head under the influence of violent passions, the local phenomena are evidently induced by the nervous influence. The active congestion of certain organs of the brain, for example, while they are in a state of excitement, is a similar phenomenon" (p. 827, p. 920 NOTE).—NOTE Q.

These several examples, however various may be the remote causes of the phenomena, are so nearly alike that they may be regarded as one,

^{*} The curative effect is to be explained by leeches operating through local nervous centers. See § 497, 893 a, c, 923 d, 939 f, 974 b, 1024 a.

and it is not less obvious that they involve the philosophy of inflammation as induced by loss of blood, or as it springs from other causes.

951, b. And now for the opposite result, which is brought about by precisely the same immediate exciting cause, the nervous influ-

ence, though not so supposed by the distinguished observer.

"When a patient," says Dr. Armstrong, "had lost only an ounce of blood, from the shock of the operation syncope came on and effectually removed an acute inflammation of the brain." Again, "a patient," says the same writer, "was so alarmed at the preparation for bleeding, that syncope occurred, and completely stopped an in-

flamination of the pleura" (See § $476\frac{1}{2}h$, 479, 955 a).

951, c. Looking at the foregoing examples in their true relations, there may be advantageously considered, besides their immediate object, certain other points which reflect a strong light upon the nature of the nervous power, the causes and mode of its development, its modifications by the nature of its exciting causes, its subsequent propagation to parts remote from the brain and upon the brain itself, and its remarkable influences upon all parts. In the examples before us we see that power variously and in unusual operation. We see that it is positively developed by excessive loss of blood, by shame, by the violent exciting passions, producing a high arterial action, or inflammation of the brain or of other parts in one case (§ 950), instantaneous injection of the cheeks with blood in another, and the brain and whole head in another (§ 951, a); and these are corresponding re-We see, also, that an exactly opposite effect is produced by the loss of only one ounce of blood, and in another instance by the operation of fear alone (§ 951, b); an acute inflammation of the brain being overthrown in the former case, and an inflammation of the pleura in the latter. The common nature of the modifying cause cannot be mistaken; and when we consider the variety of more remote exciting causes, excessive loss of blood in one case, an ounce in another, shame, anger, and fear in others, the close analogies, yet diversified results, in one series of the cases, and the absolute opposition in the other series, yet each example in this series exactly alike, though involving the loss of an ounce of blood in one of the instances and fear in the other; when, I say, we consider these things, we must admit not only the common nature of the intervening cause, but that this cause is liable to be variously modified by the agents which rouse it into action, and that, however apparently estranged from each other may be many of these agents, they modify the incidental cause in modes corresponding with the effects. A common philosophy applies, therefore, to all the cases, and this philosophy is equally true of those morbific and remedial agents which determine the same effects upon distant parts when applied to the alimentary canal, or to the skin, &c., and therefore, also, of the whole compass of remote sympathy. type of the whole is in the examples before us ($\sqrt[6]{475\frac{1}{2}}$, 500 m, 1056).

951, d. It is farther worthy of remark that the examples (§ 951, b) show how powerfully the nervous influence may be determined upon the organic constitution of the brain by the loss of a single ounce of blood, and in the case of the pleuritic inflammation by fear alone; while either case is a conclusive proof of the philosophy which I have propounded of the modus operandi of bloodletting, and that it is in no respect of a mechanical nature. These examples also demonstrate my position that the nervous influence is most profoundly felt when

syncope comes on.

952, a. Some of the finest illustrations of the effect of bloodletting upon the organic properties of the extreme vessels of the arterial system, either directly through the loss of blood, or, by alterative reflex nervous actions, are shown by the changes which take place in the

blood while flowing from the arm in inflammatory diseases.

952, b. Some of the most remarkable of the foregoing changes may be induced by a very small loss of blood. Thus, a patient of mine was attacked with pneumonia, after convalescence had begun from a protracted fever. She was placed in an erect posture, and an ounce of blood was drawn, in a full stream, into each of three wine-glasses; when syncope took place. In the first glass the blood had a thick, strong, indented, buff, and a fimbriated edge; in the second the buff was sensibly less, and the other peculiarities were diminished; in the third they had disappeared.

952, c. On the contrary, however, in a case of inflammatory fever Hewson observed the unusual phenomenon of the appearance of the

inflammatory buff only on the fourth cup.

952, d. "There is a very considerable difference to be sometimes observed in the quantity of coagulable lymph in blood taken in different cups from the same patient at the same bleeding. In some instances this difference has been observed nearly one half."—Wardrop. Sometimes more than one half.—Scudamore. "The same is relatively increased during the continuance of bleeding; and it is surprising how great a change will take place in this respect at minute periods."—Thackrah. And so Gendrin, Stokes, &c. Again, however, the foregoing phenomena are sometimes directly reversed; and an increased quantity of fibrin, and a diminution of serum, have been found in each successive cup. These conditions, too, as well as the preceding, depend, in a measure, upon the rapidity with which the blood is abstracted. Mead, the able humoralist of other days, observes, that "the blood may certainly undergo any imaginable changes by alterations made in its motions only" (§ 500 m, 687½).

952, c. If syncope take place, the blood not only generally loses its inflammatory characteristics (b), but the clot is often much softer and more voluminous. Should the inflammation afterward go on, the

blood will be found to have resumed its former peculiarities.

952, f. Blood, drawn from a person, or from an animal about to faint, coagulates very rapidly. In this case, the rapidity of coagulation appears to bear a remarkable ratio to the depression of the organic properties of the solids; as may be readily seen in slaughter-houses. But, again, on the other hand, when death is suddenly produced through the nervous system by blows on the stomach, apoplexy, &c., or by running, lightning, organic affections of the heart, &c., or when the powers of life are greatly reduced by malignant fevers, the blood generaly, though not always, remains fluid.

These seeming paradoxes are resolved by supposing peculiar influences of the solids upon the blood, according to the specific modifications of their organic properties; these, as well as all the other differences and changes, being, therefore, an evidence that bloodletting produces its effects upon the *vircs vitæ* of the solids, and that the organic properties, other things being equal, will be affected according

to the quantity of blood taken, the manner of taking it, &c.

952, g. Musgrave, in adverting to the rapid changes which take place in the blood during the operation of general bloodletting, re-

marks that these alterations "require the agency of some third power; for to suppose that the blood undergoes so sudden a change merely by the quantity being lessened, would hardly be more extraordinary, than to imagine that pouring a glass of brandy out of a bottle would turn the rest into cider" (§ 1087).*—See KRIEMER's experiment § 485.

952, h. How futile, therefore, the recent observations of Andral as to the relative quantity of lymph in inflammatory diseases! The most bloodless subjects are often liable to inflammation, and the loss of one or two ounces may affect, essentially, the proportion of lymph in the next two ounces (§ 688 ee). Here, therefore, is proof in the very nature of things, which stamps all these inquiries as humoral assumptions. Indeed, Andral, himself, had long before settled the fallacy of these later observations by the well-grounded statement, in his Pathological Anatomy, that "no one solid can undergo the slightest modification without producing some derangement in the nature and quality of the materials destined to form blood, or to be separated from it." And this, too, from the father of modern humoralism (§ 699 c).

GENERAL AND PRACTICAL OBSERVATIONS ON BLOODLETTING.

Of the General Extent of the Remedy.

953. The vital influences of loss of blood originate in the vital relations of the blood to the organic properties of the solids. The blood being the pabulum vita, the solids are extremely sensitive to any loss of this fluid they may sustain. This sensitiveness resides in the organic properties (§ 184, &c.). Inflammation and fever being also essentially constituted by a morbid condition of those properties (which are more susceptible for being thus affected (§ 137 d, 143 c)), the loss of blood, especially in general bloodletting, makes an instantaneous and profound impression upon them, by which their morbid condition is so radically altered that nature reacts at once, and sometimes completes the cure almost on the instant (§ 137 e, 151, 152).

954, a. There can be no general rule as to the quantity of blood which should be abstracted in any given case of disease, or as to the rapidity with which the abstraction should be made. This must always depend upon the circumstances of each individual case, and upon the effects of the remedy during its application, which should, of course,

be superintended by the physician (§ 675).

954, b. It is, nevertheless, certain, in a general sense, that some definite quantity of blood should be removed; and this, according to the nature of the affected organs, the character and intensity of the disease, &c. (§ 133-156). This is necessary not only to the present effects, but to the permanent influences of the remedy. This permanence cannot often be maintained without the continued operation of a certain diminished supply of blood to the general capillary system (§ 514 g, 516 d, no. 6). Dry cupping, therefore, and all similar expedients which are prompted entirely by erroneous views of the modus operandi of loss of blood, produce none of the effects which appertain to bloodletting in any of its modes. I cannot, therefore, accede either to the dry cupping of the distinguished mechanical physician, Dr. Arnott, or to his opinion "that it is a great modern improvement in the practice of the healing art, in bleeding for the cure of inflammation to take the blood away as quickly as possible; since

^{*} This conclusion was no farther theoretical, but was founded upon a common-sense view of the exigencies of the case.

intense inflammations of the brain, lungs, bowels, &c., are equally removed by faintness, whether it happens after the loss of two ounces

of blood, or of fifty."—ARNOTT'S Physics, &c.

954, c. In general bloodletting, the nearer the loss is carried to the point of syncope the more profound and permanent will be its effects. In grave forms of inflammation and fever this amount of influence is required, and perhaps at repeated applications of the remedy (§ 999).

954, d When syncope is induced by loss of blood alone it is a test that the vital condition of the small blood-vessels has been strongly affected; but more or less so, in a general sense, in the ratio of the quantity abstracted. Like the contraction of those vessels, syncope is one, though a less simple, consequence of the vital impression exerted upon them (§ 944 c, 961 e).

955, a. It should be said, therefore, in qualification of the statement in section 951, b, that it is exceedingly rare that the loss of a single ounce of blood, by venesection, will subvert inflammation of any organ, especially of the brain, even though the nervous influence be so intensely developed as to establish syncope ($\S 961, c$). The following are common examples, and go with the others to illustrate my doctrine of the nervous influence. Thus, Dr. Armstrong:

955, b. "A patient, at the point of death from acute inflammation of the pleura and lungs, was bled to the extent of fifty ounces, when he had obtained no relief. If we had stopped here, in two hours the patient would have died. After abstracting about six ounces more blood syncope came on, from which he recovered convalescent."

If this patient had been bled in an erect posture and from both arms, and had syncope followed the loss of fifteen or twenty ounces of blood, it is scarcely probable that he would have been saved.

Again, another patient of Armstrong's "had been once bled, after which the inflammation of the pleura and lungs returned. He had nearly expired from the bleeding; but the symptoms were so urgent that I determined to bleed him decisively, and I told his friends that he might perhaps even die under the operation. I bled him decisively, and syncope came on suddenly and continued some time, so that I thought he would have died. He recovered afterward with

small doses of calomel and opium" (§ $892\frac{4}{5}$, i, 1068).

955, c. Examples of the foregoing nature have been of constant occurrence, in the hands of enlightened understanding, from the time of Hippocrates, who began the example. The proper rule in extreme cases was observed, as above, by Armstrong, and was thus laid down by Celsus: "It may happen," says Celsus, "that a disease may require bloodletting when the system seems unable to bear it. Yet, if there appear no other remedy, and the patient must perish unless relieved by a rash attempt, it is then the part of a good physician to declare that bloodletting is the last resource of his art, but that it may precipitate death. Having done this, he should bleed, if desired. There can be no room for hesitation in cases like this, since it is better to try a doubtful remedy than none at all. And this ought especially to be done when a paroxysm of fever has nearly destroyed a patient, and another equally severe is likely to follow. So, also, in palsy, and, again, when angina suffocates" (§ 892 c, 892 $\frac{4}{5}$ i, 1068).

955, d. Here the importance is fully shown, not only of abstracting a certain quantity of blood, but of obtaining a full impression from the erebro-spinal influence, in many cases of inflammatory affections, as, also, the error of Marshall Hall's recommendation that "bloodletting should never be carried to actual syncope, but only to the very first signs of approaching syncope, which is, in fact, to be prevented by immediately laying the patient in the recumbent position." Many examples of the foregoing nature are presented in the Commentaries, and

others will follow in the present work.

955, e. Where bloodletting has been already carried to a large extent, yet the original disease still perseveres; or when we are called at the advanced stages of inflammation or fever, or where inflammations may spring up in subjects exhausted by long confinement, or in broken-down constitutions, the rules of practice are less precise, and depend more upon the circumstances of each individual case. But, in a general sense, so long as any severe or obstinate inflammation may be present, whether acute or chronic, we shall scarcely go wrong in abstracting more or less blood, not seldom freely, either by the lancet or by leeches. This is the dictate of philosophy, and it is enforced by the soundest experience. They are often cases, however, which demand habits of critical observation, accuracy of judgment, and an unremitting attention to medical pursuits. Otherwise, it will be often but little better than the hazard of the die. Without these requisites, where uncertainty prevails in critical conjunctures it is better to leave the whole matter to nature. In such emergencies she will oftener triumph than the unskillful practitioner, who may only embarrass her "Medici plus interdum quiete, quam movendo, proficerunt." This principle holds in the foregoing cases where art is imbecile from ignorance. And so it is from inadequate bloodletting in the early stages of inflammation and fever.

But, let it be remembered that the two most important objects to

be considered in the treatment of disease is,

1st. To adapt our remedies in all respects to the nature and existing condition of the pathological states.

2d. To carry them as far as and no farther than the institution of such a change as will enable Nature to take upon herself, most success-

fully, the work of cure (§ 857).

956. General bloodletting is the proper mode of depletion, especially after the age of infancy (§ 576, e), in all forms of fever, and in all the active inflammations of the internal viscera. This is particularly required at the beginning of the treatment, on account of the universal change which general bloodletting induces in the sanguiferous organs; thereby relieving, at once, the instruments of disease of a redundant quantity of blood, and immediately reducing the force with which the blood is distributed. There is also thus obtained a farther important advantage from the potent reflex nervous influence which is determined upon the instruments of disease by a great and sudden change of action throughout the arterial system, as well as from influences exerted upon the general vital conditions of numerous organs; the very effect upon the skin, for example, and especially upon the intestinal canal, reflecting a nervous influence upon other organs which may be the seats of disease; just as when antimony or ipecacuanha send their influences abroad in a more direct manner through the intestinal mucous tissue, or call up the co-operation of the skin with that tissue in subduing pulmonary inflammations (§ 514, h), by exciting a complex circle of reflex nervous actions.

957. On the other hand, if the treatment have been begun by other remedies, or if it have been neglected, and disease have thus acquired the force of habit (§ 539), or if general arterial excitement have existed and gone down spontaneously, or, in neglected cases, under the influence of remedial agents, even of loss of blood, and however suddenly, the results in the preceding section can be obtained only in an inferior degree by general bloodletting. Comparatively little change of action may then be induced in the vessels generally; or the effect of general bloodletting may be lost in the influence of habit (§ 539, &c.). Here, too, the remedy is on a par, in principle, with all others. Nevertheless, general bloodletting is likely to be important at any stage of visceral inflammation so long as the disease exists in much intensity; whatever treatment may have been pursued, or however the disease may have been neglected. But, should a manifest abatement have followed under any of the foregoing circumstances, leeching may then become far more efficient than venesection (§ $892\frac{\pi}{5}i$, 1008).

958, a. In the ordinary forms of active inflammation, and where practicable in fever (§ 961-970), the first bloodletting should be the largest, and this should be in proportion to the exigencies of the case. We may often accomplish all that is desirable by a single blow, as it were; which is incomparably better, in grave inflammations and fevers, than a dozen smaller ones, which may even fail, or prove detrimental, in the end, where greater decision, at the onset, would have

completed a cure (§ 950, 965).

958, b. It appears, also, from what has been said, that the operation of general bloodletting should always be conducted by the physician; and it is doubtless owing to disappointments that have arisen from consigning the application of this important remedy to the hands of barbers and leechers that it has fallen into disrepute with many. Leeching may be done by the unprofessional, because it operates upon a modified principle from that of general bloodletting; and it is much less important as to the precise quantity of blood which should be abstracted, particularly on account of slowness (§ $476\frac{1}{7}h$, 921, 937).

But, in general bloodletting, every thing may depend upon an exact effect at the moment of the operation; and that will depend not only upon the precise quantity of blood abstracted, but upon the position of the patient, the size of the orifice, the flow of the blood, the management of the patient's mind so that mental emotions shall not interfere, and upon other well-regulated influences which the skillful physician can alone determine, and alone estimate. Nor can the most experienced and gifted practitioner ever foretell, in any given case of disease, what quantity of blood should be abstracted, by the general method, under the best-regulated circumstances.

This practice of intrusting the operation of general bloodletting to the ignorant will cease to be tolerated when the *modus operandi* of the remedy shall come to be appreciated and acknowledged; nor, until then, will it undergo in the hands of the professional that just application, according to the exigencies of disease, which rarely fails to

illustrate its remedial effects.

958, c. I must now refer the reader to those divisions of my subject where the distinctions are considered between leeching, general bloodletting, and cupping, for other remarks relative to the just quantities of blood that should be abstracted in certain given forms of dis-

ease, and which were there introduced for the purpose of illustrating the distinctions between those several modes of bloodletting.

959, a. Finally, therefore, from what has been now said of the principles upon which bloodletting operates, as well as from experience, the rule as laid down by Dr. Marshall Hall, and other late writers, that "Syncope is a uniform criterion of the quantity of blood to be abstracted, and which the nature of the case may demand," is fallacious. Dr. Wardrop gives us the same rule. "The state of fainting," he says, "is to be considered an index of the quantity of blood which is necessary to be removed for the relief of the disease." On the contrary, syncope may depend on so many other causes than loss of blood, the actual tolerance at the first operation may be so little that its repetition may be indispensable soon after the patient revives, and perhaps to a large extent even before binding up the arm. These cases of early syncope, where the remedy may be appropriate, are, also, the very ones which most demand repeated abstractions of blood; and the effect produced at each application of the remedy should be the measure of the quantity to be abstracted (§ $687\frac{1}{2}$, 688 d, e, 936-938, 943, 944, 961, 967, 981–988).

959, b. "Dr. Moseley," says Robert Jackson, "advises us to bleed, ad deliquium, in yellow fever. I coincide with him in recommending extensive bleeding in this form of disease; but I do not accede to the rule which he assumes for judging of the measure. It is vague and uncertain. Deliquium occurs sometimes from the loss of a few ounces of blood, sometimes scarcely from the loss of six pounds. The act of fainting is not, therefore, a rule of dependence for regulating

practice" (§ 992, 994).—Note Ff p. 1135.

960, a. Many expedients have been attempted as substitutes for bloodletting; from the comparatively rational method by cathartics, blisters, and other subordinate antiphlogistics, to the ne plus ultra of dry cupping. It would be difficult to assign their appropriate rank, in theoretical conceptions, to some of the novelties which have been brought forward, from time to time, to fulfill, or to surpass, the intentions of bloodletting, or to banish this principal remedy from the healing art. Louis undertook its explosion with more signal success than any other champion of the "meditation upon death." (See Examination of the Writings of M. Louis, in Med. and Phys. Comm., vol. ii., p. 679-815.) Others, more inclined than Louis to lend a helping hand to nature, resort to bold experiment, whose evil results, if incident to bloodletting, it must be allowed, would consign this remedy to a well-merited reproach. Thus Pereira, in his Materia Medica, remarks that,

" I tried tobacco somewhat extensively, a few years since, as a substitute for bloodletting in inflammatory affections. But, while it produced such distressing nausea and depression, that it was with difficulty I could induce patients to persevere in its use, I did not find its antiphlogistic powers at all proportionate, and eventually I discontinued its employ-

Such, then, is the philosophy which rears itself against the welltried and faithful agent; while it is regardless, by its own showing, of the disastrous results of agents long since condemned as fruitless and destructive, and would vainly endeavor to "substitute" them for the safest and only effectual remedy for all grave inflammations.

When Pereira undertook to "substitute tobacco for bloodletting in inflammatory affections," it was with the full knowledge that its use had been mostly abandoned, as wanting in curative virtues, and hostile to life; that surgeons, even, had greatly forsaken it as an enema in strangulated hernia, on account of the frequent deaths it had produced (§ $892\frac{3}{4}b$, 893n). It was mainly such diseases as confirmed dropsy, tetanus, intractable ileus, and hydrophobia, that were handed over to its tender mercies. Nay, more; our able author says of it, himself, as employed for the relief of dropsy, that,

"In small doses, it is an uncertain diuretic, and in larger doses it causes such a distressing nausea and depression, that practitioners

have long since ceased to use it in dropsical cases."

How many perished under the experiment with this unmanageable poison in Pereira's attempt "to substitute it for bloodletting in inflammatory affections," either from the direct effect of the poison, or from the neglect of bloodletting, our author does not say; though confessions here would have been some atonement to science and humanity.—Note H p. 1117.

Nor may the contemners of bloodletting, and of those who commend its judicious use, in the treatment of inflammations, complain when "their poisoned chalice is thus commended to their own lips."

Were we to contrast the victims of tobacco, alone, during its rage as a panacea, with such as may be assumed to have fallen, through all time, by the lancet, it will not be denied by the stoutest prejudice that the odds are fearfully on the side of the poison. It is profitable, therefore, to pursue this inquiry, and to interrogate yet farther the disposition which may exist in the most enlightened quarters to hold on upon the worthless, but deadly engines of the Materia Medica. The tendency may be, at least, to induce a greater toleration of the useful means, and thus to compensate, in a measure, for the effects of poisons when administered in what are regarded as their therapeutical doses.

We may, therefore, consult another eminent writer of our own day, the able author of the American Medical Botany; though he does not say, nor have we reason to think, that he had "attempted to substitute tobacco for bloodletting in inflammatory affections." I make the quotation, therefore, to show how there will sometimes escape from the best writers and practitioners an apparent justification of the worst practices humanity is called upon to encounter; and to contrast the tacit acquiescence of all in commendation of poisons which operate with deadly effect in their authorized doses (and not unfrequently conceding, at the same time, the consequences here alleged), with the denuciations of bloodletting which are wafted from transatlantic shores to startle Americans into mute astonishment.* Thus, then, our author:

"At the present day," he says, "tobacco does not seem to be extensively in use, having passed into neglect rather because more fashionable remedies have superseded it, than because it has really been weighed and found wanting."

In this respect, the able writer is manifestly at fault; and if we only turn over this same leaf from which I have made the quotation, we

shall read on the next page as follows:

"This powerful medicine has been also employed with some palliative effect in hydrophobia, and certain other spasmodic diseases. Its internal use, however, requires great caution, since patients have,

^{*} This must now be qualified, as at p. 760 note, and Note Mm p. 1141.--1865.

in various instances, been destroyed by improper quantities administered by the hands of the unskillful or unwary. Notwithstanding the common use and extensive consumption of tobacco in its various forms, it must unquestionably be ranked among narcotic poisons of the most active class. The great prostration of strength, excessive giddiness, fainting, and violent affections of the alimentary canal, which often attend its internal use, make it proper that so potent a drug should be resorted to by medical men, only in restricted doses, and on occasions

of magnitude."

Here, then, we are justly told that tobacco should be used with caution even in hydrophobia. And, suppose it could be said of bloodletting, as the writer affirms of tobacco, that "patients have, in various instances, been destroyed by improper quantities," even though a part of the injury might be ascribed to "the hands of the unskillful and unwary;" the advocates of the remedy would scarcely allege, on seeing it fall into disuse, what the foregoing writer does of tobacco, that "it has passed into neglect rather because more fashionable remedies have superseded it, than because it has really been weighed and found wanting." No; they would acquiesce upon the ground that it "had been weighed and found wanting." And now suppose, again, that such "weighing and wanting" were plausably affirmed of bloodletting, as is conceded, in reality, by its best advocates, of tobacco, even in the hands of the best practitioners,—in their own hands, or only through ignorance and carelessness alone, the remedy would be so hunted down that the rational treatment of inflammations and fevers by bloodletting would probably subject the practitioner to public odium. Indeed, we know that this was remarkably the case with the illustrious Robert Jackson, when he first began the explosion of the tonic and stimulant treatment which prevailed so fatally in the British Army. He was generally denounced as "a murderer" by the British Doctors; till the astonishingly diminished mortality in the British Army soon showed them who the real murderers were (§ 569, e). On the other hand, however, with what calm indifference we contemplate the ravages of the tonic and stimulant treatment of fevers, and the no less inconsiderate use of the most violent agents of the Materia Medica, for the mere purpose of devising some expedient that shall do away with the necessity of bloodletting in acute inflammations and fevers! (§ 1065, c, d, 1068, a).*

As to tobacco, in the treatment of strangulated hernia, we possess in tartarized antimony, or even in the lobelia inflata, far better and safer means for establishing a relaxation of the muscular system; especially in the former agent. Nay, in very many cases, bloodletting, to the extent of syncope, will not only accomplish the intention as fully, but bestow the immense advantage of subduing any inflammation of the intestine, which is so apt to be produced by strangulation. Besides the immediate hazard of life which is incident to enemas of tobacco, there is the great objection, that should it fail of its contemplated purpose the prostration which it occasions will render an operation by the knife of very doubtful result, but which might have been perfectly safe before the administration of the tobacco. The patient will be little apt to bear the superadded shock which is inflicted by so severe an operation; and the intestine, too, in a state of inflammation which will now contribute greatly to the same general ex-

^{*} Notes F p. 1115, H p. 1117, GG p. 1138, Мм р. 1141.

haustion. And since the question, among surgeons, has turned mainly upon the abstract effect of tobacco as an agent of immediate death, and witnout much reference to those ulterior results, and since it is no proof that a remedial agent does not destroy because the patient survives its immediate operation, I may also say that its pernicious tendency reaches these cases in the obstacle which it places in the way of subsequent bloodletting, which is often important to the patient soon after the reduction of the intestine, if it have not preceded it (§ 576, e).*

But, it is not alone this or that agent, or other individual means, which has been attempted as a substitute for bloodletting in the treatment of inflammations. The whole class of poisonous agents to which tobacco belongs has been declared on high authority, as we have seen (§ 891, c), to be "the most important medicines we possess." And to justify yet farther what I have said of British therapeutics, and to sustain the contrast with American philosophy and practice (§ 349 d, 3503 k, kk, 709, note), I shall quote Pereira's Materia Medica relative to his opinion of opium when compared with the uses of bloodletting, cathartics, antimonials, &c.

"Opium," he says, "is undoubtedly the most important and valuable

* The fascinations which attend tobacco as a luxury led to its extensive use as a remedy for disease; and the question arises whether, from what is now known of its pernicious effects when applied to the gastro-intestinal mucous membrane, and even to the skin, in health as well as disease, its moderate use as a luxury can be justified by the physician? This question I shall briefly investigate, for another purpose, also;—that of illustrating yet farther certain peculiarities of remedial agents in relation to vital habit

(§ 535, &c.).

There could be little doubt, upon principle, that the various modes of using tobacco would be detrimental in most conditions of disease, on account of the increased susceptibility of organs (§ 137 d, 150, 151). But it would be still a question of facts in relation to this particular agent (§ 650). The requisite facts are before us, and are decisive against

the luxury in morbid conditions.

But, his does not prove that the moderate use of tobacco will injure the health of those who are in possession of health (§ 137, d). We cannot reason, as I have endeavored to show, from the effects of remedies upon man in health to man in disease; excepting as it respects their violence when manifested in healthy subjects. Of this principle tobacco affords a very full exemplification, and shows that the principle is equally true in its opposite aspect, and that we may not reason from the effects of an agent which is deleterious in disease to its effects under the condition of health; as, indeed, is shown by food

itself.

We must, therefore, take the facts in all the cases, and what other facts teach us as to the constitution and laws of organic beings, and as agents operate upon different parts. With this kind of philosophy, we are enabled (unexpectedly, according to the usual method) to decide that the moderate use of tobacco is rarely deleterious in health, and has, therefore, but little, if any, tendency to abbreviate life. The law of vital habit, as well as observation, enables us, also, to know that the habitual, is safer than the interrupted, use of tobacco; so, only, there be no excess. The insusceptibility, which the continued use establishes, soon passes off on suspending the influence, and leaves the interface of the passes of the passes of the properties of the passes of the passes of the properties of the passes of the passes of the properties of the passes of the pas dividual more or less liable to nauseating and other morbific effects, on resuming the lux-ury. If this be often repeated, it would probably lead to chronic or other forms of disease (§ 535, &c.).

There is, therefore, a remarkable difference between the ultimate effects of the habitu-

There is, therefore, a remarkable difference between the ultimate effects of the habital aluse of tobacco and of most other poisonous agents of the Materia Medica. The narcotics, for example, are constantly morbific, while continued in their moderate therapeutical dose, though less so by use than at the beginning. But this is not true of many of the ordinary causes of disease, which observe a coincidence with the effects that arise from the habitual and interrupted use of tobacco. The miasmata which lay the foundation of fever are examples (§ 544, 550, 551, 552 a). This brings into view the differences in the vital constitution of different parts of the mucous system, and the examples are clear illustrations of those distinctions, since, in the case of the poisonous agents of the Materia lustrations of those distinctions; since, in the case of the poisonous agents of the Materia Instructions of those distinctions; since, in the case of the poisonous agents of the Materia Medica (including tobacco), they exert their influences upon the mucous tissue of the stomach and intestine, while tobacco, as a luxury, and miasmatic agents, are mostly operative upon other parts. The same is seen in the skin, since tobacco will not establish the habit of endurance in that organ (§ 136, 137 b, &c.). Tobacco is also another witness, in its associated aspects as a luxury and as a poison, against the doctrine of operative hard second control of the same control of the sam tion by absorption.

remedy of the whole Materia Medica." "Its good effects are not, as is the case with some valuable medicines, remote and contingent, but they are immediate, direct, and obvious; and its operation is not attended with pain or discomfort. Furthermore, it is applied, and with the greatest success, to the relief of maladies of every day's occurrence, some of which are attended with the most acute human suffering. These circumstances, with others not necessary here to enumerate, conspire to give to opium an interest not possessed by any other article of the Materia Medica;"—and certainly not by bloodletting.

And now suppose that the Author of these Institutes had made the same affirmation of opium, instead of having bestowed the like commendation upon bloodletting in his former work; he would have cheerfully acquiesced even in the misrepresentations of his Commentaries by the British Medical Press, and in the countenance afforded by the British Medical Profession of the great injustice inflicted upon himself, as an atonement for the injury he might have done.—Note Wp. 1127.

Nor did I scarcely do justice to the cause which I endeavor to advocate, when, in a former section, I spoke of the influence of the British "Association" in their concerted action to overthrow the fabric of Medicine, and to raise upon its ruins the absurdities of a foreign Chemist (§ 349, d). The record should have been also made that the work on "Organic Chemistry applied to Physiology" had been a year before the Profession, ere its successor, the work on "Animal Chemistry applied to Pathology and Therapeutics," was "communicated to the British Association for the Advancement of Science," and "Edited FROM THE AUTHOR'S MANUSCRIPT, BY WILLIAM GREGORY, M.D., PRO-FESSOR OF MEDICINE in the University and King's College," and before other distinguished British medical writers became the systematic In-TERPRETERS of the Author's meaning, as well as Champions of his doctrines (§ $350\frac{1}{2}$, $350\frac{2}{3}$, $447\frac{1}{2}f$). The hurricane, I say, swept over the Nation, and such was its force upon the Continent, and even in America, that the learned in those Countries had serious doubts of the stability of any science, and that the great bulwarks, which had been slowly and progressively reared by the observation and wisdom of a long series of ages, would be, hereafter, at the mercy of any aspirant. For all this, the British Nation must and will be held responsible (§ $1062\frac{1}{2}$ –1065, 1068, a.)

And now, let us remember, that when radical and enduring changes may be wrought in any science which is built upon the foundations of Nature, and when, especially, the phenomena have been open to all, they will hereafter advance as slowly, at least, as the errors had sprung into existence. The wisdom of one generation is, at most, but a shadow in advance of the last; and, however discoveries may come up in the open field of Nature, the great laws which have been educed from what was known in the past will be of no easy subversion. Nor can I doubt, that come what may to Medicine, we shall sooner or later go back to Hippocrates, and begin a reconstruction upon the foundations which his genius and observation had laid $(376\frac{1}{2}, 376\frac{3}{4})$.

Developments of important facts in science and in art may advance with rapidity; but, even those details, which are apt to grow out of principles already known, are commonly progressive according to the sum of knowledge which may be handed over by one generation to the next succeeding. It is not, however, equally true, that a portion,

or the whole of mankind, relapse into ignorance, speculation, and superstition, through the same gradual process. The decline of the Roman Empire, and the subsequent darkness which overshadowed the earth for six hundred years, or the later fall of Spain from the highest to the lowest rank among the nations of Europe, are a melancholy commentary upon the rapid and disastrous influences of luxurious ease, and arbitrary opinion, upon knowledge and philosophy, and illustrate the tardy pace of the human mind in regaining its independence, recovering the path of Nature, and retrieving what it has lost. Nor is it an improbable conjecture that the serious failure of a harvest in Europe, or any serious impediment to the outlet of British manufactures, or an ascendency of *Puseyism*, would soon place our Ancestor by the side of Spain.

But, practical examples in bloodletting are the best demonstrations of the utility of the specific objects contemplated in the present article. I shall therefore supply another, which may be derived from the distinguished Mr. Liston, so able in surgery, and who advises

"Every practitioner to think twice of the probable and possible effects in every case of disease before he determines upon and proceeds to

open a vein for the purpose of draining off the vital fluid."

This distinguished surgeon also recommends the use of aconite for the cure of erysipelas (§ 892½, d). Just now, also (1845), Dr. Fleming (President of the Royal Medical Society of Edinburgh) appears with an able work on the same most destructive agent; and, although agreeing with him, most entirely, as to the value of this remedy in neuralgia, when topically applied, and there be no active inflammation, every consideration of experience is opposed to his declaration, that,

"Aconite not only effects a cure in a shorter period than any other mode of treatment, in acute rheumatism, but appears to possess the great negative advantage of not increasing the liability to extension of the dis-

ease to the membranes of the heart."

The great difficulty with bloodletting in acute articular rheumatism has consisted in its too limited application; and if the remedy, as is said, be chargeable with the vice of lighting up the disease in the heart, it is for the foregoing reason (§ 893 n, 950, 965, 1000, 1001). Bouillaud is thought to have occasioned no little of this mischief by "copious bloodletting," and mainly because of his expression,—"coup sur coup." But, he rarely ventured beyond a pound or two of blood; and this quantity was made up by successive bleedings,—"coup sur coup." His practice, therefore, was but a feeble resuscitation of that far more successful treatment, in France, by copious abstraction of blood.—(Med. and Phys. Comm., vol. i., p. 325, 326.)

Finally, I hold that the internal use of aconite is inadmissible in all active forms of inflammation, and endangers life under all circumstances of health or disease. Had Dr. Male, of Birmingham, who employed this remedy to the extent of some eighty drops of the tincture in four days, in augmented doses varying from five to ten drops, for the relief of simple, chronic pain in the back, upon the recommendation set forth in the work by Dr. Fleming, been as obviously the victim of bloodletting as he was of the aconite, it can hardly be doubted that such a case would have been marshaled against bloodletting in all

forms of disease.—Note H p. 1117.

Nor will I neglect this opportunity of objecting to the proposition

of Dr. Graves, of Dublin, that belladonna, instead of blockletting, should be employed in those congestive fevers in which cereoral disease is attended by contraction of the pupil, and upon the ground, mainly, that belladonna so affects the brain as to produce a dilatation of the pupil. It is evident, however, that this reasoning is fallacious; for, if belladonna be given in any of the common forms of cerebral disease that disease will be aggravated in proportion as the pupil dilates under the influence of this agent. In justice, also, to the remedy which I advocate, I may say, if its applicability rested on no better foundation, and if, especially, surrounded by the same objections as belladonna, its recommendation would be justly regarded as rash and unphilosophical (§ 469, 476 c, 487, 488 $\frac{1}{2}$, 500 h, 569, 892 d, 906, motto, d).

960, b. It may be also difficult to say, whether the mere negative pretext for loss of blood, such as dry cupping, or the substitution of violent internal agents without a plausible apology, or the more common and exclusive dependence upon cathartics, and other acknowledged but minor antiphlogistics, has been most destructive of life. Certain it is, however, that they who most discourage bloodletting are generally the greatest advocates of the violent agents of the Materia Medica. And, it is not a little astonishing with what calm indifference we contemplate the ravages of this unmitigated practice, or the tonic and stimulant treatment of fevers; and more especially when the consequences are alienating multitudes to the soft embraces of

homoeopathy (§ 857, 878, 893 n).—Note H p. 1117.

960, c. I have already stated my opinion that, among the sequelæ of morbid anatomy as originally taught by the modern Parisian school, and adopted by others, is the system of "Specialities;" a name sufficiently significant of its dismemberment of medicine. To this innovation upon a comprehensive science, whose parts can be no more separated, and viewed in the abstract, than any one of the great organs of life can be separated from the rest, and yet go on with its own functions and the residue of the shattered whole with theirs, may be traced up many of the great errors in practice as well as in medical philosophy (§ 129, 137 e, 163, 638, 685, 686). That the "special" system was an immediate emanation from the hospitals of Paris is evident not only from the natural relations of the pursuits, but from the fact, also, that they sprung up together. Nature thus became disjointed; every thing in disease took on the aspect of materialism; nothing was to be seen but lesions of structure within, and blotches and scabs upon the surface; one kind of fever was located in the liver, another in the spleen, and dropsy in "Bright's disease of the kidneys." Medicine was cut up, in the Parisian hospitals, into numerous fragments, and brought under all the details of the mechanical principle of "a division of labor." Much, however, is owing to an ignorance of the laws of the nervous system in their relations to disease. But, it is also to the same method, in part, that we must ascribe the attempts of a smaller number to substitute tobacco, belladonna, aconite, &c., for bloodletting, in the treatment of inflammation and fever; and it is upon this ground that Magendie was led to imagine that he had produced, in the presence of his class, yellow fever in dogs, and typhus fever in cats (§ 744), and which, especially, has induced many to believe in the matchless virtues of quinia as displayed by Piorry

when he attempted the dislodgment of intermittent fever from an in-

durated spleen (§ 892, k, 892 $\frac{4}{5}$ i).

960, d. But, it is not alone the intrinsic nature of the fundamental evil which has introduced the new system of teaching medicine. There never was a time when so many zealous aspirants were commended to places either by clamors, or by the force of industry. The revolution was also only a part of the fashion of the day; and its precipitation harmonized exactly with the achievements in medical chemistry, and other analogous varieties in the wide field of philosophy. Fortunately, this corruption has not yet fastened itself upon the Medical Colleges of Great Britain or America; and the hope may be therefore entertained that the worst of it has passed (§ 1008).

960, e. Nor will I leave the foregoing allusions to the comparative value and abuse of the great agents for disease, without referring to the general apathy which is manifested at the havoc which the whole band of empyrics are dealing out with their domestic engines of death; while, were the lancet equally common in their hands, and only now and then a startling slaughter, that solitary result would rouse the in-

dignation of the profession, and disturb the peace of society.

960, f. The advocates of bloodletting have sometimes affected its reputation by the mere language in which it is recommended. They are said to be rash; and bloodletting shares the odium. Thus, Dr. Elliotson, in speaking of enteritis, remarks, that "The first thing one has to do is to bleed the patient well. You must set him upright as he can be, and bleed him from a large orifice without any mercy." The prejudiced, or unreflecting, look only at the language; but an upright posture, and a large orifice, render the operation safe, and compara-

tively mild, though it proceed, as it should, ad deliquium.

960, g. I have no doubt that much of the antipathy to bloodletting has grown out of an illusion natural to the fears of man. It is not wholly predicated of debility; for we constantly meet with admonitions against its use in high inflammations, which are not remarkable for their prostrating effect. But, there is nothing more deeply implanted than the knowledge of the immediate importance of the "vital fluid" to the life of every animal; and this conviction has been farther roused into operation by perverting the authority of Holy Writ, that "in the blood is the life thereof;" though, had Scripture said that in Calomel, Jalap, and Emetic Tartar, or Tobacco, Aconite, Lobelia, and Brandreth's Pills, is the death thereof, the quotation would have been hourly apposite. We are, also, dead in a few seconds from the division of a large artery; and we scarcely see a difference in the rapidity of the result when this method, or a division of the medulla oblongata, is employed for the destruction of life. Hence, many come to associate bloodletting, as practiced for the relief of disease, with the extreme method of effecting death. I shall not dwell upon this want of philosophy, but shall only now say, that it is the same defect which leads the objectors to bloodletting in disease to its constant application to pregnant women, and to others dying of apoplexy, or from the shock of a fall, or from drinking cold water, and where there may have been no other inducement for the practice than the capricious desire of the subject, or the prejudice of society. I shall, however, endeavor to indicate still farther the fallacy of the latter practice, and to point out, as it respects disease, some of the principal causes which

modify the necessities of the system in relation to its ordinary supply of blood, and how it sustains the privation by the same contingent influences.

960, h. Let us, finally, have a word upon the doctrine laid down and so well understood by Hippocrates, that, "Severe diseases require

severe remedies" (§ 906, motto, e).

From what has been said under the general consideration of Therapeutics, it appears that this rule is to be received in a broad, not a universal, sense (§ 906, f). We have seen, for example, that it is remarkably liable to exception in small-pox, &c. This grows out of the nature of the predisposing causes of disease, which alter the properties of life according to the nature of each agent. Each one, as I have said, affects them in kind, and in a way peculiar to itself. We have seen this impressively exemplified in the self-limited diseases; and it is shown in the morbific effects of all the agents of the Materia Medica. One will alter the vital states, either in health or disease, more profoundly and more permanently than others. Such, also, is the principle upon which depend the hereditary predispositions to disease. Then we have those dormant changes which constitute the predisposition to idiopathic fever, and which may be in a state of incubation for a year or more before the final explosion.

In all such cases, the properties of life are more or less permanently affected, though not profoundly, till an explosion of more absolute disease shall follow; but often as the result of a long and imperceptible series of morbid changes. In tuberculous phthisis, cancer, syphilis, &c., the properties of life are deeply, as well as more permanently and obstinately affected, and it may be impracticable for art to induce such changes as shall place the diseased states in a recuperative condition; though disorganization may be now the main obstacle.

Then we have the varieties and gradations of febrile and inflammatory diseases, which, according to the nature of the predisposing causes, either yield spontaneously, or submit readily to appropriate remedies, or the force of disease may be too intense for active treatment (§ 961).

Here, too, we derive important lessons from experience, in a more restricted sense, which go with what experience has reduced to principles in respect to the modifying effects of the remote causes of disease, in establishing the principle that the treatment of disease must be governed by the existing pathological states, and with a reference to the nature of the predisposing causes, and that great modifications may be necessary in diseases of a common genus, though all the cases may be distinguished by equal violence, and by many prominent phenomena that may be very analogous. It is now, therefore, that we find the general rule, that "severe diseases require severe remedies," may demand a great modification (§ 52, 137 d, e, 143 c, 150–152, 163, 650, 666, 670, 673, 674 d, 675, 685, 686, 847 g, 854 d, 856 b, 857, 858, 859 b, 861, 863, 868 b, 870 aa).

The application of the rule will depend, I say, in a general sense, upon the nature of the remote causes, the organs affected, and the extent in which the restorative principle is impaired. A vast variety of diseases require no aid from art. Others, again, like pneumonia, enteritis, &c., require a prompt and energetic interference. But, again, there are maladies of great violence, as in the examples already mentioned of small-pox, measles, scarlatina, &c., in which the same

treatment cannot be pursued, in a general sense, as in many diseases

whose symptoms are much more violent (§ 961, 964, 976, c).

It might, therefore, seem that Nature is here contradicting herself. But it is far otherwise. The apparent contradictions are only illustrations of her perfect consistency, and of the great laws that morbific causes alter the nature of the properties and functions of life according to the virtues of each cause, and that artificial impressions can be salutary only in proportion as the morbific causes impair the recuperative principle. But, owing to constitutional peculiarities, and various incidental influences, the disposition to the restorative process in the self limited diseases may be more or less impaired, or inflammation of important organs may supervene, when Nature will require the intervention of art, according to the existing modifications and complications of disease. Again, as in the hot stage of fever, the very recuperative efforts of Nature, if I may say so, are often so excessive as to result in actual increase, or in developments of, disease, and therefore require the interposition of art for a certain degree of restraint (§ 675). These principles will be now illustrated by the effects

Of Bloodletting in the Congestive Forms of Disease.

961, a. It often happens that idiopathic fever is attended with venous congestion of one or more important organs; and, as we have seen, it is the tendency of this inflammatory condition of the venous tissue to embarrass the organs of circulation, especially the heart. The same peculiar influences are sometimes witnessed in the inflammations of other tissues; particularly in the advanced stages of phthisis pulmonalis (\S 961, f). In all the congestive forms of disease, especially when of an acute nature, the general susceptibility of the system to the loss of blood is increased. I may also say that the prostration which is induced by venous inflammation is quite different from that which results from inflammations of any other tissue (§ 135-137, 140, 150). It is also greatly different from that which attends the cold stage of fever. In the first case, very morbific nervous actions are reflected upon many important organs, and, unless artificially relieved, the powers of life may sink rapidly to a state of extinction. Nature is, as it were, knocked down, and is incapable of a recuperative effort. In the last cases, however, the impression is manifested chiefly in the circulatory system. There is not that profound lesion, in the absence of venous congestion, which prevents the recuperative effort: and hence it probably always happens in pure fever that reaction soon follows the stage of depression (§ 675, 764). Something like the converse of this is seen in those erysipelatous inflammations of the throat which sometimes give rise to an apparently great commotion of the system. But, if there be no great amount of abdominal disease attendant on these cases, the reflex nervous action is expended upon the circulatory apparatus; when any remedy that will relieve the throat will be followed at once by a subsidence of the arterial excitement (§ 140, 927 b). But, these cases are apt to be complicated with obscure, though severe congestive disease of the abdominal organs, especially of the liver, which has thrown deeply a morbific predisposition over many other parts, and which, in consequence, feel more profoundly the influences propagated by the intense inflammation of the fauces In such instances, however, the general arterial

excitement is less than in some of the violent affections of the fauces which may be greatly of a local nature, or where any accompanying abdominal disease may be of a different nature from congestion (§ 689 1, 973), and according to the nature of the reflex nervous actions.

961, b. Venous congestion, independent of fever, is a common form of disease, and manifests the same tendency, as when connected with idiopathic fever, to embarrass the organs of circulation. But, this is only a contingent effect; since the general manifestations of the disease in respect to the circulatory apparatus exist in a subdued form of that excitement which attends the ordinary forms of inflammation (§ 390 b, 688 c-k, 786, &c., 978). But, when venous congestion becomes suddenly aggravated, or other causes may increase the susceptibility of the system so that the congestive disease may be more sensibly felt in its sympathetic influences, there often takes place a general prostration of the animal functions, and a very impaired condition of the organic, through a peculiarly alterative reflex nervous action.*

It is, however, in congestive fever that we witness the strong demonstrations of venous congestion in generating extensive and profound lesions through its very morbific reflex nervous actions. This is especially true if the local disease exist at the invasion of the constitutional malady. It has then already shed a malign influence in connection with the predisposition to the general disease; and, as these influences progress together, they come in with intense force when the explosion takes place, and, unless art should now interpose, the diseases go on mutually exasperating each other, and calling into existence other congestions, or inflammations, which make all haste to join in the circles of disordered movements (§ 143, 514 h, 666, 902 g). presence of venous congestion not only aggravates the constitutional disease, but, in itself, modifies the nature of that affection for the worse (§ 786, &c.), prolongs the stage of intense morbid action (§ 764, a), often prevents the succession of the hot stage, and does its own peculiar part in overthrowing the organic functions; often exerting its malign influence till subdued by art (§ 927). Here, too, it is that art must make its demands upon science more extensively, more deeply, than in any other conditions of disease. The proper management of bloodletting, cathartics, &c., or whether a stimulant shall be first administered, or whether under the most appalling aspects of the combined force of disease we shall leave all to Nature till she will admit of help, are often problems upon which life is poising at the moment, and can be resolved only by the enlightened physician.

But, it commonly happens that remedial aid may be promptly and efficiently administered; and, it will be my purpose, therefore, to indicate that system of treatment which is demanded in a vast propor-

tion of the cases (§ 1056, 1068, a).

As a preliminary step, I must refer the reader to what I have said of the pathology of venous congestion (§ 786-818), and especially to the Medical and Physiological Commentaries, for the proof of the inflammatory nature of venous congestion, and its dire effects upon organic life. It is also important to add, in this place, that although there exist more or less apparent prostration of life in the aggravated conditions of venous congestion, and of active phlebitis, as, also, in congestive fever, the term is here employed in a conventional sense, and not as significant of debility, or of any necessary depression of

* The blood often gravitates from congested veins after death, especially of the liver, leading to a false conclusion that there had been no such affection (§ 699 c, 800).

vital action. The circulatory organs are, indeed, often more or less sunken in their action; but the immediate instruments by which the morbid processes are carried on are actually exalted in their organic properties. These properties, too, are now greatly diverted from their natural state; and it is that alteration in kind which essentially constitutes the local condition of disease, and from which arise its morbific reflex influences, and it is this, and the partial loss of voluntary control over the muscles of animal life, which have led to the doctrine of debility (§ 410, 476 c, 487 h, 500 h, 569, 639, 743, 746, 780, 915–921, 999 b).—Note Ff p, 1135.

961, c. In consequence of the foregoing morbid state, the sudden abstraction of two or four ounces of blood, in congestive fevers, uterine phlebitis, &c., will often produce syncope. But, where the complications consist of the ordinary forms of inflammation and venous congestion a greater loss of blood will be sustained at its first abstraction; though generally less than when the same inflammation is unattended with congestion (§ 137 d, 140, 476 $\frac{1}{2}$ h, 803, 804, 806, 973).

961, d. In the foregoing cases a small loss of blood will frequently create a greater tolerance of the remedy; especially if syncope supervene. It happens, therefore, in numerous cases, that we may proceed, soon afterward, to abstract sixteen to forty ounces without producing syncope. The first impression on the organic properties so modifies their condition and lessens their susceptibility, and mitigates the force of disease, and releases the embarrassed circulation, that the subsequent and greater loss of blood often fails of producing any powerful influence, unless carried to a pretty large extent. Dr. Burnett, in describing the congestive fevers of the Mediterranean, says, "it will often happen, after a few ounces of blood have flowed, that syncope will be induced. But, in the course of an hour the bleeding may generally be repeated, and thirty or forty ounces may be taken away without producing syncope." Such has been often my experience.

961, e. In cases of the foregoing nature there is more or less determination of blood from the circumference, and its consequent accumulation about the right cavities of the heart, by which this organ is embarrassed in its action, generally contributes to the early syncope. Among the results of the vital change effected in the capillary vessels by a small loss of blood is their immediate expansion, and a returning equilibrium of the circulation. It is true that loss of blood, by increasing the contraction of the capillary vessels, increases, also, the determination of blood upon the heart; and it is in part, as I have said, for this reason, that a small loss of blood often overpowers the circulatory organs. But, when syncope passes away, this state of the circulation, and other morbid phenomena, will have been more or less subdued. The influence of loss of blood which results, as a primary effect, in increasing, or producing a contraction of the capillary blood-vessels. is so essentially different from that of the morbific cause which determines, apparently, the same phenomenon in the cold stage of fever, as in the analogous conditions of venous congestion, that it alters the morbid state, and thus places the vessels in a way to undergo an active expansion; or reaction, as it is called. And herein we witness a critical instance of the alterative nature of loss of blood, and how its influences are exerted, and how apparently the same phenomenon is not the same, and may be, therefore, due to even opposite causes (§ 150-152, 650, 1039, 1040, 1056, 944 c, 954 d).

961, f. We sometimes observe a similar prostration of the circulatory organs from acute inflammation, when attended with pain, especially of the intestines. Here, too, is the same inability at first to bear the loss of blood, and the same tolerance created by its abstraction (§ 961, a). Thus, Dr. Wardrop: "A gentleman was seized with acute pains in his bowels, accompanied with a good deal of tenderness on slight pressure, along with some degree of febrile excitement. On opening a vein in his arm, only a few ounces of blood were removed, when the pulse sank and he fainted. In two hours afterward I bled him again, and he did not fall into a state of syncope until he had lost about thirty ounces of blood" (p. 79, Note as to pain).

Many examples of the foregoing nature occur in the "Commenta-

ries.

962. When syncope is produced by a small loss of blood, and by the loss alone (§ 938), and where this remedy is demanded, the disease is serious, and will probably require one or more prompt repetitions of general bloodletting. Nothing short of this treatment will be likely to subdue the obstinate venous congestions which are the usual cause of the prostration of the system, and of the intensity of the febrile force, if complicated with this constitutional form of disease.

963. If mental causes, or intestinal irritation, have contributed to early syncope, we may generally proceed to the farther abstraction of blood soon after the patient revives, which, in the cases now under consideration, is commonly important (§ 937). If loss of blood, alone, have been the cause of the early paroxysm, a longer interval (four, six, or eight hours) may be most expedient, or necessary (§ 794, 795, 801). The state of nervous influence decides the whole.

964, a. In the cases now supposed, the prostration is sometimes so great that it may be necessary to create a tolerance of loss of blood by previous stimulation, or before resorting to the repetition of bloodletting (§ 961, b). And here, too, enlightened experience abounds in

the records of medicine. Thus:

"Immediately upon the application of warmth to the surface," says Dr. Gallup, "take a little blood; perhaps two, four, six, or eight ounces, according as the patient may bear it. If he be a little faint, it is nothing but what is common; a little time will remove it. He will soon bear a second bleeding in this condition better than the first."

Aretæus not only describes this condition of disease, but advises the same enlightened practice, especially if the congestion be the occasion of great prostration and "syncope." "Venas itaque in cubito protinus cædito, multumque sanguinis, sed non semel totum mittito; imo, et bis, et ter, alio die, quo interim vires instaurentur repitito." Alexander of Tralles discourses in the same manner upon this subject. The language of A. Paré is remarkably graphic in describing the treatment of the Plague and "Pestilent Diseases." It corresponds with the best philosophy of our own day.

"So soon," he says, "as the heart is strengthened and corroborated with cordials and antidotes, we must come to phlebotomy and purging." "You may perceive that the patient is ready to swoon when that his forehead waxeth moist with a small sweat suddenly arising, by the aching or pain at the stomach, with an appetite to vomit, and desire to go to stool, gaping, blackness of the lips, and sudden alteration of the face into paleness, and, lastly, most certainly by a small and slow

pulse: and then you must lay your finger on the vein, and stop it untithe patient come to himself again, either by nature, or else restored by art; that is to say, by giving him wine, or any such like thing: then, if you have not taken blood enough, you must let it go again, and bleed so much as the greatness of the disease or the strength of the

patient will require or permit" (§ 8924, i).

964, b. No injury can grow out of the use of stimulants in these cases while the powers and actions of life are so morbidly affected as to be still more injured by the loss of a small quantity of blood. In these cases, bloodletting, without previous stimulation, impairs still farther the vires vitæ, which are now too morbid to react under its influence, and it increases, permanently, the determination of blood from the circumference to the centre.

964, c. In other cases like the foregoing disease is so intense at its invasion, and Nature so little recuperative, that it may be impossible to create a tolerance of loss of blood. No reaction appears in these cases, and all such patients must perish (§ 149, 150, 794, 795, 801, 808 b). Nothing will rouse an exciting reflex nervous action.

964, d. At other times, even in the active forms of inflammation, the power of the system to bear the loss of blood may be destroyed by other remedies. Thus, it frequently happens in croup, that emetics, especially of tartarized antimony, render bloodletting impracticable, particularly when they produce catharsis instead of vomiting; and the patients may then die from their inability to sustain the necessary loss of blood. Thence appears the importance of carefully considering their relative order in the administration of remedies, especially where loss of blood may be essential. I am certain, from observation, that bloodletting has lost its reputation, with some, in pneumonia, &c., from its having been applied unsuccessfully under the prostrating influence of tartarized antimony, and when, in consequence, the powers of the system would only admit of a moderate loss of blood, and would not bear the superadded depressing nervous action.

965, a. Dr. M. Hall, and some other writers, suppose that the power of the system to bear an increased loss of blood is owing to an increase of disease; which appears to me an important practical error. On the contrary, the first bloodletting generally diminishes the activity of inflammation, however it may subsequently acquire its original or greater force. It is true that an increase of inflammation will act in the manner supposed; but it does not thence follow that there has been an increase of disease in other cases because the patient bears a second better than the first bloodletting. Indeed, in the cases now before us an increase of the venous congestion after the first bloodletting often diminishes the tolerance of loss of blood, on account of the peculiar influences of that form of disease. This, too, is especially apt to occur where the abstraction of blood has been inadequate to the exigencies of the case; and these cases, in consequence, have brought great disrepute upon the remedy, though it be the only practice that supplies a chance of relief.

965, b. When too little blood has been abstracted for the exigencies of the disease, although frequently repeated, it may increase the force of the malady. Inadequate depletion so modifies the organic powers that it rouses them into greater energy; the whole circulation becomes released from its embarrassment in the capillary system;

and the heart being thus, and in other ways, set at liberty and invigorated in force, propels the blood with increasing violence. This mechanical influence, in itself, lights up the flame of disease, and kindles it in other parts already disposed to join in the disordered movements. But much is also due to an augmented irritability of the instruments of action; when irritability would probably have been lessened by a greater loss of blood. The effect produced by the smaller loss, in rousing and otherwise modifying the general capillary action, reflects a stimulating nervous influence upon the immediate instruments of the local malady, which, in its turn, had equally sustained, in the more direct manner, an exalted state of action; and thus are instituted circles of reacting sympathy between the general and local capillary vessels (§ 982-1003). The same results, it is true, with the exception of the morbific, attend the loss of blood when carried to the extent of its curative influences (§ 961 d, 966, 994 b, 1005 e). The remedy, therefore, in all grave visceral congestions, as well as in inflammations, should reach the point of absolute depression. The powers of life are then not only subdued in energy, but the strength of the impression places them in the way of the recuperative process (§ 961 e, 1056, 1068).*—Notes Ee p. 1133, Ff p. 1135, Gg p. 1138, LL.

966. Leeching is absolutely inadmissible in the foregoing forms of disease. It is now a great object to relieve the heart of its morbid sympathies with the capillary system, and of the accumulated blood, and thus establish something like an equilibrium in the organs of circulation. But, since it is the primary effect of loss of blood to produce a contraction of the capillary vessels, and to thus determine an unusual volume of blood upon the centre of circulation, that mode of bloodletting should obtain which is least obnoxious to these objections (§ 921). This is general bloodletting; and although it increase the general contraction of the small vessels, its impression is then so rapid that it more or less subverts, with a corresponding instantaneousness, their morbid state. An immediate dilatation of the vessels is the consequence, the blood circulates with greater freedom, and thus the heart is enabled to throw off the accumulated blood; while the favorable change induced in the extreme vessels moderates or removes their depressing reflex nervous action, by which the heart is farther roused into increased energy (§ 921, 934, 944 c, 965 b).

967. The prostration of which I have spoken in this division of my subject is commonly mistaken for debility (§ 469, 476 c, 487 h, 488½, 500 h, 569). Stimulants are therefore too apt to usurp the place of bloodletting and other analogous means, and to occasion a frightful mortality. On the contrary, there should be no delay of that decisive use of the remedium principale which may be demanded by the exigencies of the case. Seize the first moment that nature is ready, should any preliminary steps be required (§ 964, a), or she will soon advance to a more forbidding state, and baffle the well-directed efforts of art (§ 863, d, 999 c-1007, 1019).—Notes Eep. 1133, Ffp. 1135, It.

968. Since, therefore, it is always important to do as much as may be requisite, and as nature may admit, at the early stages of disease requiring the loss of blood, we must not be deterred by early syncope from early attempts to abstract the quantity of blood which the exigencies of the case may seem to demand. It is astonishing how soon, in congestive fevers, the morbid powers of life will rally under the

^{*} It is a paradox to most that a large loss of blood may be curative when a smaller would be fatal, but the former perhaps unnecessary to life (§ 1001, 1005~g).

loss of a few ounces of blood, and how soon we may subsequently

proceed to a more decisive use of the remedy.

969, a. Where venous congestion is associated with idiopathic fever, and the stage of reaction appertaining to the constitutional disease has come on, the prostrating influence of loss of blood is vastly lessened, and far greater quantities are often borne at its first abstraction; and this especially, as will appear in the next following division of our subject, if some active form of inflammation be also attendant; though even now it oftener happens that a second bloodletting is better sustained than the first. In all these cases the several forms of disease constantly interchange modifying reflex nervous actions, and these modifications are as constantly varying, either spontaneously or through the operation of foreign causes.

969, b. It will appear, also, that simple venous congestion of the brain sometimes manifests a strong exciting influence upon the organs of circulation; when bloodletting is borne, at its first application, to an extent which never obtains under the usual depressing influence

of the disease (§ 688 c-f, k, 806, 978).

969, c. Although it be generally true that it is the tendency of venous inflammation, whether in its active form, as in phlebitis, or in its sub-active, as in venous congestion, to depress the general circulation, and, when the latter is attendant on idiopathic fever to delay the stage of reaction, and that it is the usual effect of loss of blood to increase that depression, progressively, till syncope comes on, there are, nevertheless, numerous instances in which the remedy manifests an opposite effect. That is to say, relief may be so instantaneous that the pulse will increase in volume and force, the dark and trickling blood spout out with a florid hue after a few ounces have escaped, and while still flowing from the arm.* In these cases the abstraction of blood should be continued till the pulse is again subdued, or the ne-

cessary impression will not be produced (§ 806, 1056).

969, d. So variable in intensity are the morbid changes in the different varieties of congestive fever, especially the local congestions, as in the plague, yellow fever, typhus, &c., at different times, that an impression exists with many that those diseases must be treated at one time with stimulants, while bloodletting may be necessary at another. But this is neither true nor philosophical. On the contrary, since the same disease is always essentially the same (or there is an end to all medical philosophy, § 752, &c.); and since also disease is most intense and malignant where bloodletting is, at first, most imperfectly borne, if this agent be important in the mild forms, it is more so where the prostration, and, therefore, the amount of disease, is greatest. This, too, is universally sustained by all the best experience (§ 1005. Also, p. 868–872, § 1068).—Notes Ff p. 1135, KK.

970, a. Cases not unfrequently occur which present many of the phenomena of the prostrated conditions of venous congestion, and congestive fever, which have no affinity with those diseases, but which are constantly confounded with them. Such is the case with injuries from falls, the shock of surgical operations, &c. Here the powers of life are actually and simply reduced; certainly not modified as by

the action of specific morbific causes (§ 790 b, 961 b).

970, b. In the latter instances the abstraction of blood has been often fatal, and should never be practiced unless some inflammation

* See KRIEMEE's experiment p. 310, \(485.

subsequently spring up. But if the prostrating nervous influence be great, even though the brain have sustained concussion, stimulants should be administered. This should also be the practice in the analogous conditions which are produced by drinking cold water when in an excited state from the united effect of hard labor and hot weather. Opiates should be also employed to relieve the stomach. In apoplexies, when the pulse is sunken bloodletting should be delayed, or cautiously practiced at first. The morbid state of the brain, or pressure on the organ, has determined, in such cases, a perniciously depressing influence on all the powers of life, and the impression from loss of blood superadded to this morbid influence may destroy the patient at once. Bloodletting will be ultimately necessary, and perhaps to a large extent. It commonly happens, however, that an opposite or exciting nervous influence is determined upon the heart and capillary vessels, at the invasion of apoplexy; that the pulse is full and bounding, the face flushed, &c. In these cases, decisive bloodletting, cathartics, &c., are the principal remedies.—(Med. and Phys. Comm., vol. i., p. 342-361; vol. ii., p. 234-238.)

970, c. There are many sympathetic affections supervening on congestive disease of the abdominal organs which appear to most observers to be the leading condition of disease; such as diffuse inflammation of the mucous tissue of the fauces, erysipelas, painful affections of the head, &c. These, however, as I have before said, should be considered rather in the light of symptoms, while the essential means of cure should be directed to the primary and principal seat of disease (§ 689, l). In the cases supposed, many different tissues may be affected, and there may be, also, much variety in the morbid states. There is congestion (sub-inflammation) of the venous tissue of the liver, &c., more active inflammation of the fauces, or of the skin. But, the mucous tissue of the stomach, and intestines, is also more or less severely affected, and the head suffers sympathetically. These last conditions, however, are not inflammatory, perhaps; but so nearly approximate that pathological state that they are readily converted into it by any increasing force of hepatic congestion (§ 803), by the undue irritation of cathartics, or by improper food, stimulants, &c. (§ 527 d, 528, 529). All other parts suffer, also, more or less, in their vital states; and, although variously, there is yet determined throughout, by the leading conditions of disease, a general coincidence between the morbid states that may be strongly pronounced and those which are less so, and where predisposition is only taking place (§ 143 c, 150-152, 870 aa). This may be more distinctly appreciated by referring to what I have said of the influences of remote causes (§ 630 c, 652, 657 a, 659, 689 l, $694\frac{3}{4}$, 813, 817, 847 g, 1058 m).

I am now brought to the application of the foregoing remarks. We see, therefore, from the analogy which prevails throughout the morbid states, how a single remedy, like loss of blood, will strike a blow at any one of the pathological conditions; and the more profound its influence upon the principal, the more completely will it subvert the minor affections. But loss of blood is far from being always necessary in these complex conditions; and we may then find that some internal remedy, as, for example, a compound of six or eight grains of the submuriate of mercury, twelve or twenty of jalap, and one to five of ipecacuanha, will stretch its power to every part of

the organism, touch every part with a corresponding salutary influence, and start every part at once on the way of recuperation (§ 143, $233\frac{4}{5}$, 514, 674 d, 733, 804, 811, 847 g, 1056, 1059).

The foregoing example is also a good illustration of an important doctrine which I have propounded to explain what humoralism had neglected; the exemption of all parts of the body from any deleterious action of the blood in those local forms of disease which are capable of modifying its character. The blood is always affected in nearly one universal way in any given condition of disease; whatever the sympathetic complexities. The whole condition of the solids, from the highest to the lowest grade of disease, moves on under reciprocal harmonizing influences of all parts upon each other, though the greater malady exert a controlling power. The morbid blood, therefore, is exactly adapted in its condition to all parts, and, therefore, molests none (§ 137 e, 143 c, 847, 870 aa, 984).

Of Bloodletting in the recognized Forms of Inflammation.

971. Although I have demonstrated in my Essay on Venous Congestion, contained in the Medical and Physiological Commentaries, that its pathological state is constituted by inflammation of the venous tissue, the subject, notwithstanding its importance, has received as yet but little attention from the hands of others; but stimulants, as usual, especially in Great Britain and France, continue to be the favorite means of treatment; though not so, nor ever so, in these United States. The decision of the right still rests with futurity; but that future, in the prospective view of America, in the rise of the North of Europe, and the retrospective view of Southern Europe, cannot be distant.*

972. I now approach, however, conditions of disease which have been, from immemorial time, of an admitted inflammatory nature: however various the hypotheses as to their pathological cause. We now lose sight, or mostly so, of that depressing influence of venous congestion which so often gives malignancy to fever, and embarrasses or disarms the hand of art, and are in the midst of innumerable modifications of the same pathological state as presented by other tissues, that reflect upon the system a series of different influences, though

often of an intensely morbific nature (\S 935, d).

973, a. To comprehend fully the effects of loss of blood in the inflammatory conditions now before us, it is still important to bear in mind the reciprocal sympathies among the capillary vessels of all parts and with the heart, as set forth in the preceding divisions of our subject, since upon them depend, as in simple forms of venous congestion and active phlebitis, the disturbing reflex nervous influences of all local inflammations. But these constitutional results, although dependent upon reflex actions of the nervous system as when they spring from venous congestion and active phlebitis, present an aspect more or less different. The local conditions exalt, instead of depressing, the general action of the circulatory organs. There is an expanded, instead of a contracted state, of the general capillary system; the circulation is free, the heart unincumbered with accumulated blood, and beats with more than its natural vigor and frequency. These inflammations, therefore, commonly act upon the system at large after the manner of direct stimulants, and thus tend to counteract the depressing effect of loss of blood (§ 226, 229, 500 m).

^{*} The stimulating treatment of all diseases has become very general in the U. S. A. -Notes F p. 1114, H p. 1117, EE p. 1133, Fr p. 1135, Mm p. 1141,-1865.

973 b. The point, therefore, to be now observed is an apparently oposite effect of reflex nervous action, excited by inflammation, upon the organs of circulation from that which attends the loss of blood or any other sedative agent. One is exciting, the other depressing. One

excites general arterial action, the other subdues it.

974, a. Certain parts, under equal degrees of common inflammation, maintain the general exciting influence upon the organs of circulation against the depressing effects of bloodletting more than others, and this is especially true of the brain (§ 230). In many forms, also, of specific inflammation, as in acute rheumatism, the local vessels are in a peculiarly irritable state, and produce an excessive exciting influence upon the whole sanguiferous system; the heart itself often participating, by sympathy, in the rheumatic inflammation (§ 525, 526 b, 527). Something in this respect is also due to the nature of the tissue which may be the seat of the affection; articular rheumatism, for example, deriving an obstinate character from the peculiar vital constitution of the ligaments (§ 133, 134). Here the affection may yield only to great losses of blood; especially if the chief dependence be placed upon this remedy. Owing to the same persistence of local disease, and its general influences, cathartics make less impression than in most other active inflammations, unless of the brain. For the same reasons, also, gradually-increased doses of the antimonials are commonly borne to a large extent, and vascular action yields slowly to their influence. A common principle is concerned with all the remedies, according to their developments of reflex nervous action.

974, b. On the other hand, when inflammation, in rare instances, is aggravated or induced by an excessive loss of blood, such is the combined nature of the exciting cause and its curative effects, that the modified irritability of the vessels may readily yield, at the moment, to a farther loss; but if general bloodletting be now practiced, it will

soon go on with its deleterious influence (§ 950).

974, c. Inflammation of the brain develops very powerfully and obstinately an exciting nervous influence, which not only holds in subjection, against the usual influence of loss of blood, the whole capillary system and the heart, but this nervous power is determined upon the vascular system of the brain itself with greater intensity than upon the instruments of inflammation in any other part (§ 227, no. 1, 230). Hence it is, that general bloodletting is commonly necessary to a greater extent in inflammations of the brain than of other organs. This is the reason, also, why general bloodletting is required by the cerebral inflammations and congestions of infants, when leeching will often succeed in inflammations of equal intensity in other parts at that period of life (§ 576 e, 925 b, c, 951 b, d, 955, 992, 944 c, 1056).*

period of life (§ 576 e, 925 b, c, 951 b, d, 955, 992, 944 c, 1056).*

975, a. Again, another general law. So great is the sympathy between vessels of the same order, and especially those in which the organic properties are most active, that while those which are engaged in the process of inflammation remain unsubdued the whole series throughout the body is liable to be thus held in a state of excitement. This is peculiarly true when the brain is the seat of inflammation; for, while the contraction of its capillaries tends, as a sedative, to prostrate the general circulation, their morbid excitement, on the other hand, not only contributes to sustain the general circulation, but the influence of a stimulant is, by this cause, still exerted upon the organ,

and still propagated to the heart and arteries (§ 226, 229, 230, 480-483, 500, 526 a, 916-921, 929-936). The excitement of the vessels of the brain is partly promoted by their peculiar relation to the organ which is the principal centre of the nervous power, and in part by the tendency of that condition to prevent a contraction of the corresponding vessels in other parts. This peculiarity depends upon a special nervous influence which is exerted upon the vessels of the brain in a state of inflammation (§ 231), and is thus distinguished from that condition of the vessels in other parts when the seat of inflammation. In inflammations of other organs, therefore, the nervous influence by which excited vessels hold in partial subjection the corresponding series throughout the body is less, and is sooner overcome by loss of blood, and general prostration follows sooner, than when the brain is the seat of inflammation (§ 140, 1039, 1040).—Note Hh p. 1138.

975, b. Hence the reason why greater loss of blood is generally necessary in cerebral inflammations to produce syncope than in similar affections of other parts. In the latter cases, and where general bloodletting is used, the capillaries of the brain are brought under impression as soon as the loss is felt by the instruments of disease; and the depressing nervous influence then becomes a powerful co-operating cause of the general prostration (§ 930-934, 940-942). But, it is now obvious, that when the brain is the seat of inflammation this influence is obtained with greater difficulty. Before it can be established by loss of blood a positive change in its highly-excited capillaries must be effected, and that opposite state of nervous influence which arises from their excitement must be first overcome (§ 944 c). This depression may be often obtained most perfectly, and propagated most extensively, by long-continued syncope. This will sometimes happen in most inflammations of other parts, and sometimes of the brain itself, by the loss of small quantities of blood (§ 951 b, 955 b, 1056).—Also p. 920 Note.

975, c. We learn from the foregoing philosophy the reason why, in cerebral inflammations, there is oftener a rise of inflammation after syncope from loss of blood, than in inflammations of other parts. But, in all the cases, if a repetition of the remedy be required, the same influences will, in a general sense, operate again, and again enable us to abstract all the blood that may be salutary at the next operation; and so on, till a permanently salutary change is established.

976, a. Again, in certain diseases where the cerebral and ganglionic systems appear to be much involved, but in an unknown manner, and where, perhaps, there are no special marks of inflammation in any part of the body, vast quantities of blood may be lost without inducing syncope. In these cases there is great nervous irritability. I have seen upward of thirty ounces of blood taken from the arm of a man, in hydrophobia, after the radial artery had ceased to be felt; the patient being all the while in an erect posture, and remaining to the last without any sense of faintness. Similar cases are recorded by the East India surgeons.

976, b. On the other hand, we have an opposite state of the cerebral influence in some cases of mania, and the delirium of drunkenness, where, from its depressing effect, the condition of the system has been erroneously compared to that of debility (§ 569, d). In some particular cases bloodletting is imperfectly borne; evidently from its strong impression upon the nervous centres. In the case of drunk-

enness there is venous congestion of the brain, and so modified by the remote causes as to often lead to early syncope (§ 816 b, 978).

976, c. Analogous modifications will also arise from any peculiar manner in which the organic properties of other parts may happen to be affected; not only in specific inflammations, but from those shades of difference which attend common inflammation (§ 652 c, 722). Particular influences will be determined upon the whole system by these modifications, according to the nature of the combined influences transmitted to the nervous centres, by the exact modification of disease and the special influences it may exert on other parts, and give a corresponding direction to loss of blood (§ 150, 151, 228, 500, 514 h). Thence it will appear that much will depend upon the natural relation of other organs to the nervous centres, and to other parts of the body, and the special vital constitution of each (§ 133–138, 143–152).

Other, and more accidental causes, may contribute to these results. They have all an important bearing upon the effects of loss of blood, often playing an important part in the phenomena of bloodletting; leading to syncope from the loss of an ounce of blood where we may have calculated upon a pound or more, or where yet more may be demanded by the exigencies of the case. The effect, therefore, of loss of blood may throw, at once, a flood of light upon some obscure condition of disease, as some ill-defined venous congestion, or upon some natural peculiarities of constitution, &c. Or, again, it may be useless, or hazardous, to bleed a patient far advanced in typhoid pneumonia, or in the pleurisy of confirmed phthisis, or in less serious inflammations incident to the scrofulous diathesis, or in the phlegmatic temperament.

It is therefore manifest, that peculiar impressions will be determined upon the nervous centres by the loss of blood, and thence reflected with varying effects upon other parts, according to the natural constitution of each individual, the nature, extent, force, duration, and organic lesions of disease, the organs affected, especially if the brain be its seat or otherwise participate, and according to the nature and extent of the cerebral derangement, and the nervous influence which may be exerted by this and by other parts (150, 151, 892 ½ i, 1008).

977. But it cannot be too strongly urged, that in abstracting blood, and in the administration of cathartics, emetics, antimonial alteratives, &c., it should be considered that it is the constant tendency of an inflamed part to prevent a contraction of the capillaries of other parts, and therefore to maintain the action of the general circulatory system (§ 933, 944 c). We shall not obtain a proper amount of this general impression, if important to the case, until the loss of blood is sensibly felt by the part inflamed; and this may depend upon a great variety of circumstances, even upon the contingency of a large or small stream of blood, the posture of the subject, the state of his mind, &c. But, in all severe inflammations the general impression should be fully produced, and this is only effected at, or near the point of syncope; the patient being always in a sitting or elevated posture.

978. Although, as we have seen, it is the tendency of venous congestion to depress the powers of circulation, there are many chronic cases of this disease in which the law relative to inflammation of other tissues is found to obtain, though in an inferior degree. The pulse is more or less excited and hard, and loss of blood is more or less borne, at the beginning of the treatment, as in the other cases. This

is especially true not only of chronic, but of the more rapid form of the disease, when affecting the brain. The chronic conditions, however, sometimes become suddenly aggravated, and the general circulation sinks down suddenly under this aggravated state, when syncope may follow a small abstraction of blood (§ 688 c-k, 786, &c., 976 b).

979. From the foregoing considerations it appears that general bloodletting is the great remedy for all inflammatory affections of important organs, with those exceptions of a chronic nature to which leeching is more appropriate, and which occur in that division of our subject for the purpose of illustrating its philosophy (§ 914, &c.). There should be no hesitation, in the active forms of this disease, with the most cautious practitioner, in meting out a full measure of the capital remedy. The tendency of the affection to sustain the system under the loss of blood, and the phenomena of increased excitement, should nerve the weakest arm to an obvious, easy, and important duty. This duty, however, it is my purpose to enforce yet farther, when I shall have reached the experience, and the details of practice, that remain as the choicest legacies of the illustrious dead.—Note Hh p.1138.

980. The foregoing remarks upon the tendency of inflammation to sustain the system under the loss of blood, and the rapidity with which small losses, in venous congestion, will place the organic properties in a state to bear a measure which would prostrate the organs of circulation in health, are farther illustrative of the great law of adaptation, by which nature has contrived all things in organic life for

its ever-varying exigencies (§ 143 c, 733 d, 847 g, 870 aa).

Of Bloodletting in Simple Continued, and Simple Intermittent Fever.

981. Where fever is not complicated with local congestions and inflammations loss of blood is not often required, unless to reduce the force of arterial excitement when so considerable as to endanger the appearance of those local affections. If this condition, or any condition of the febrile action, do not soon abate under the influence of cathartics, an emetic, and appropriate alteratives, recourse should then be had to general bloodletting; though it will not be often necessary to carry the remedy beyond a moderate extent. If the treatment, however, be early and judiciously begun, the disease will commonly surrender, in its early stage, without the co-operation of the principal remedy for those conditions of fever which are associated with inflammation and venous congestion.

In the cases of high arterial excitement to which I have now referred, it is important to consider that three principal causes are in operation which may lead to the development of inflammations. The most important is the morbid and highly irritable state of the capillary and extreme blood-vessels. The second is the force of the circulation, which contributes, as a mechanical cause acting upon the morbidly susceptible vessels. The third is the augmented volume of blood in those vessels, and whose influence is chiefly that of a vital

stimulus (§ 137 d, 710 b, 784).

982. But, it often happens, as when fever and venous congestion appear in connection, that inflammation presents itself simultaneously with the constitutional malady, or the latter may be preceded by either local form of disease, or these local states may spring up in the progress of the general malady (§ 779, 813). In the last two in-

stances, the affection which is first in order contributes more or less as an exciting cause of the supervening disease (§ 714, 715, 779). If the general disorder then continue to advance, congestions or inflammations of other parts are liable to spring up in quick succession; the general affection, and the local developments, and the predisposition of organs to inflammation or congestion, being the principal causes of the successive explosions of disease, and mutually aggrava-

ting each other (§ 137 d, 714, 715).

983. From what has been now said, and of the treatment of inflammation and venous congestion, we may make up our minds that there can be no tampering with the complicated forms of fever, whether associated with one or the other of the local conditions of disease. In either case, especially in continued fever, general bloodletting is more imperatively demanded than by either of the local conditions in their independent state; and the earlier this important step is taken the better. Nor should we strike with a sparing hand, nor move at a tardy pace; but rather let the first be a heavy blow, and as oft repeated as the foe may rise, yet always proportioned to its own degree of strength. Let those, however, who may not relish this "rash advice," gather wisdom and moral courage from the experience and philosophy that yet await us from abler hands.

984, a. Nevertheless, in the complications of intermittent fever with venous congestion, and sometimes with inflammation, such is the nature of the predisposing cause, and the local affections are so apt to be imbued with its influence, that it frequently happens that bloodletting may fail of the requisite impression upon the local forms of disease, and the special aid of the Peruvian febrifuge, or analogous means, may be useful, or necessary, in subduing the local affections after a due impression has been made by loss of blood, cathartics, &c. In advanced typhus, stimulants, bark, and strong broths are important.

984, b. The foregoing reference to the remote causes of disease with a view to some special deviation from the general principles of treatment is exactly on a par with the antidotal treatment of poisons. The quinia, which may be ultimately necessary to overcome intermittent fever, or its associated inflammations and venous congestions, presents a remote resemblance to the elaborate ferruginous mixture in cases of poisoning by hydrocyanic acid, and other analogous examples. It is true, that, in the latter cases the counter-agent acts in a purely chemical manner, while in the former the special agent operates through vital influences alone. I have thus adverted to this analogy in deference to the humoral pathology, and especially on account of a vague belief that quinia cures intermittents by neutralizing the miasmatic poison (§ 662, 809–816, $891\frac{1}{2}k$, 892b, $892\frac{1}{2}v$, 894c, d, 1059).

But the whole of this philosophy will be set right by considering the modus operandi of the best antidotes for poisonous doses of opium; namely, coffee and the cold dash. Here there is no difference, in their acceptation as poisons, between the opium and the miasma.

have equally established their morbific effects.

And now as to the "antidotes for opium." Who ever imagined that coffee removes the morbid states by entering the circulation, and there neutralizing the opium? The modus operandi is the same as I have set forth for opiates in § $891\frac{1}{2}$ g, k, and for the cold dash and seton in § 514 d, 905 a. I need not add that the modus operandi of

quinia, in the cure of intermittents, is exactly equivalent to coffee and the cold dash in that of poisoning by opium*(§ 137 c, 150-152, 662 a, b, 892 b, c, 904 c, d), and the nervous system will alone explain.

In all such cases, therefore, the special treatment may be considered antidotal; since, as in the cases where we merely attempt to neutralize a poison while it yet exists in the stomach, we equally apply the treatment in the former case to certain specific effects which have resulted from causes which are alike distinguished by very special virtues. In one case we attack the cause itself; in the other, the effects

which it may produce.

It is therefore sufficiently evident that in the administration of quinia in the treatment of intermittent fever, and in other analogous examples, we leave, more or less, the general principles which apply to the generic character of the diseases, and turn some agent of special virtues against the modifying influences of such predisposing causes as are capable of bending the general pathology from its more common form. But, it is rare that the general plan of treatment is not more or less in demand; or that the special remedy will come under the law of universal adaptation till the whole system is submitted to influences by such remedies as are consistent with all the varied coexist-

ing pathological conditions (§ 847 g, 870 aa).

Some other examples of practical importance will, at the same time, advance our philosophy upon the subject under investigation. Thus, bloodletting may, or may not be necessary in a scrofulous inflammation. If it attack the lungs, it will be important; especially in its early and active stages. Here the remedy is of universal adaptation. If the superficial lymphatic glands be the seat of the affection, leeches may be proper. But, in such cases, we are apt to leave the general principles of treatment, and to refer specifically to the nature of the predisposing cause, which is here implanted in the constitution of the individual (§ 561, 586, 659, 661, 666). Experience has shown that iodine, which does not belong to the remedies for common inflammation, is especially adapted to certain states of scrofulous inflammation. But, it is only to subdued forms of the disease that it is suited; while loss of blood is universally applicable in all the active grades of the disease, whatever be the part invaded, and may place every part, and the whole system, in a condition for the salutary effects of iodine (§ 137 e, 143 c, 150, 151, 163, 870 aa, 892 b, $892\frac{1}{2}v$).

Again, if the inflammation be syphilitic, and the constitution be invaded by its predisposing influences, bloodletting, cathartics, &c., may or may not be necessary. But, a general antiphlogistic plan should be pursued; at least so far as to exclude stimulating food, which may be all that the case will require (§ 856). In a general sense, however, we should have a more direct reference to the nature of the remote cause, and administer mercurial preparations; since ex perience has shown this to be the safest and most efficient treatment. Here, then, mercury assumes the character of what is called "a specific" (§ 865, 892 aa); though it is one of the antiphlogistics which fall within the principle of general adaptation to inflammatory diseases (§ 662, 859 b, 872 a, 890½, 892 b, c, 898, 900, 904 c, d, 1059).

984, c. When speaking of expectorants, and at other times, I have stated the importance of deriving our indications of cure from what we may witness of the results attendant on the recuperative efforts of

^{*} This agrees with the effects of a strong infusion of coffee in health. So, also, Emmert found that coffee increases the violent action of nux vomica (§ 903).

nature (§ 862, 863, 892 $\frac{4}{3}$ i). I am now led to recur to the subject on account of the great abuse of the principle in the treatment of acute inflammatory affections of the lungs by stimulating expectorants; which are administered for the reason alone that expectoration is one of the consequences of the natural process of cure. On looking a little farther, however, we find that bloody mucus, and pure blood, are often expectorated in pneumonia, and in incipient phthisis; and that hemorrhages are frequently occurring, as the consequence of congestion or inflammation, from all parts of the body. Here, then, is a remedy for inflammations of all parts, suggested by Nature; while expectoration refers to one part only. What is thus inculcated as to the practical application of the more comprehensive principle is enforced by all the most enlightened experience (§ 863, f).*

985. Finally, when bloodletting is judiciously practiced, it often supersedes the use of a long train of other remedial agents which may ultimately bring relief, or lessens their number and dose, substitutes the milder for the more energetic, prepares the way for their quick and salutary effects, and saves to the patient much suffering, and se-

cures a speedy convalescence.

Of Bloodletting in the Cold Stage of Fever.

986, a. Bloodletting has been practiced successfully by many physicians in the cold stage of intermittent fever. It is not, however, with any reference to this consideration that I have given to the subject the distinction of a chapter by itself; but for the greater purpose of illustrating still farther the influences which are exerted by the loss

of blood, and the instrumentality of the nervous system.

986, b. That the disease should be thus suddenly arrested is entirely conformable to what I have said of the modus operandi of bloodletting, and goes to confirm the philosophy. The capillaries being then in a state of universal contraction from disease, if loss of blood have its special influences upon the organic properties of these vessels, it should be the effect of such a cause, in suddenly, greatly, and universally increasing that contraction, by alterative reflex nervous influences, so to modify the morbid state as to interrupt the succession of the hot stage. But the abstraction of blood must be carried to the point of syncope, that it may thus determine a powerful nervous influence upon the instruments of the morbid process; or that change will not be established which is necessary to prevent the stage of reaction. In these cases, however, the necessary quantity of blood is commonly small; and syncope, therefore, is easily induced. But, as the morbid contraction depends upon a different cause, and as the vital properties are differently affected from what bloodletting produces, although the remedy occasion the same phenomenon, it often happens that no inconsiderable loss of blood will be sustained before that change can be established in the small vessels which is necessary to perfect the contraction which is incident to bloodletting, and which is the precursor of syncope (§ 1040, 1056, and "contraction" § 944 c).

987. How, therefore, shall we interpret by any other philosophy than that which I have propounded the sudden interruption of fever in its cold stage by the loss of a small quantity of blood, when no amount, perhaps, would have arrested the disease if taken at any other period? The quantities, also, necessary to success depend, in part

^{*} See Notes F p. 1114, Fr p. 1135, Gg p. 1138, It p. 1139.

upon the precise period of the cold stage; whether at its beginning, or near its termination in the hot stage. Less is necessary, cateris paribus, in the former than in the latter instance; although nature, in the latter case, is preparing for a recuperative effort (§ 675). And so the result will be influenced by the application of the remedy during the first paroxysm, or by its delay till a later, and this often in proportion to the delay. It is true, diseases generally yield most readily in their forming stage; but in intermittent fever the disease may be said to be renewed, in a measure, at each paroxysm. Like other affections, however, it acquires more or less obstinacy from the force of habit, and from the influence of local inflammations and venous congestions which so often spring up in its progress. But that habit is more or less broken during the intermission; when Nature is aiming at restoration (§ 557, &c.).—Note K p. 1119.

988, a. Here, also, may be shown absolutely the error of all the mechanical hypotheses which have been put forth as to the philosophy of bloodletting, and which have so extensively governed the application, or, rather, have led to the neglect, of the remedy. If we consider the prevailing one, that loss of blood operates by mechanically reducing the volume of the circulating mass, and thus empties the enlarged capillaries in inflammation and in the hot stage of fever, it is at once contradicted by the immediate and salutary effect of the loss in the cold stage of fever, when the same capillaries and the same instruments of disease are already so contracted that the blood has receded from them toward the central part of the circulation; while the immediate effect of the loss of blood is to determine an increased volume upon the capillaries (§ 910, 935).

988, b. It is, however, unnecessary to pursue the inquiry; but it is well to advert to the fact that the phenomenon now before us is equally demonstrative of the error of imputing syncope to the reduction of blood within the cavities of the heart; since, in the cold stage of fever, blood is always accumulated about that organ, and as the contraction of the capillaries is farther increased by loss of blood, so, also, is the central determination (§ 935).

For the full understanding of the foregoing subject, the inquiring reader will refer more extensively to what has been said of the agency of the nervous power in determining the effects of loss of blood.

989. The foregoing considerations enable us to understand why bloodletting is more useful just as the subsidence of the hot stage begins than at its earlier periods. Nature is now consummating her efforts at relief. The capillary vessels are every where about to contract to their natural volume, as a consequence of another modification of their vital state, and differing, therefore, from that of the cold stage, and from that which is induced by loss of blood. The secretions are about to break forth in virtue of this recuperative process, and bloodletting will now accelerate what nature is instituting. At any other stage of reaction this curative effect is less, since nature does not then so co-operate with the remedy as when the hot stage is on its decline. Should syncope, even, be induced during the rise of the hot stage, reaction will be very apt to return, though it pursue a mitigated course. A much smaller loss of blood will also subdue the general circulation when the hot stage is beginning to decline than during its rise, and leave a more permanent impression upon disease. Nevertheless, the

violence of reaction, &c., may be such as to increase or give rise to local inflammations; and where this is apprehended, or for the relief of pain, general bloodletting should be practiced early (§ 675, 863 d, 1003). This section involves diversified agencies of the nervous power.

Of Bloodletting in Apoplexy.

990, a. The modus operandi of bloodletting, as well as the adaptation of this remedy to the special circumstances of disease, and its critical influences according to those circumstances, especially in its relative effects through the instrumentality of the nervous power, may be now advantageously considered by contrasting its results in certain states of apoplectic affections with what has been said of the counteracting nature of inflammation, and of the nervous influence, in preceding sections. This influence must apply equally to all the cases.

990, b. It is the well-directed application of bloodletting which constitutes the principal means in the treatment of sanguineous apoplexy; and although it may be often important to delay the abstraction of blood, it will be generally necessary in the progress of the cure. Such, indeed, is the concurring opinion of almost all writers of eminence; although it is a remarkable fact that the practice is not founded upon successful experience, or any agreement in pathological views. Even those who condemn bloodletting in pneumonia, enteritis, or other grave inflammations, are neither intimidated by age, nor by expiring nature, when apoplexy makes its invasion. Some are prompted by a supposed rupture of a vessel, which they expect to stanch by bleeding from another; while a few, more philosophical, regard the effusion as the result of a morbid process analogous to secretion. It is with all, however, a mechanical operation. There is too much blood in the brain, and it must be drawn off by the lancet. That is their modus operandi, and that the extent of it. Hence the disastrous results of indiscriminate bloodletting in apoplexy. But, if the philosophy which I have set forth as to the operation of loss of blood be founded in nature, it will readily appear that the sudden and violent lesions of the brain in apoplectic affections offer us cases for great and unusual discrimination as to the time, extent, &c., of the remedy; while, also, they confirm that philosophy, and enforce the importance of an enlightened understanding of the principles through which bloodletting operates. It is said by Clutterbuck, that "there is perhaps no disease the treatment of which requires to be so much directed by theory or general principles as apoplexy. The practice in general use is, for the most part, unnecessarily violent; and, in some respects, contradictory. Bloodletting to an unreasonable extent, vomiting, purging, blistering, sinapisms, and a great variety of other stimulants, have all been administered with an almost indiscriminate and unsparing hand; as if, to insure recovery it were only necessary to have recourse to sufficiently active means, without much regard to their nature or effects."

990, c. Besides the importance of a proper reference to the influences of bloodletting in cases of apoplexy, there are often present certain inscrutable conditions of the brain which are liable to embarrass the most enlightened judgment. It is often impossible, for example, to understand the exact pathological condition of the brain, upon which the due regulation of bloodletting may essentially de-

pend. If there be hemiplegia, it is almost certain that extravasation of blood has taken place. This condition, with the rare exception of the rupture of a diseased artery, is indicative of venous congestion of the brain, with which inflammation may coexist (§ 803, 805). We have, therefore, in these numerous instances, a formidable condition of cerebral disease, and a laceration of the cerebral substance. Again, however, there may be only a state of venous congestion, or of scrous effusion, or some pathological condition which is not denoted by any visible signs after death. With the exception of paralysis, the phenomena may be exactly the same in all these conditions of the disease at its invasion. In the first two varieties, bloodletting, sooner or later, is probably necessary, in almost every case, to overcome the morbid action; though its early application may induce, or hasten, a fatal result. In the last two, which are known as scrous and nervous apoplexy, the loss of blood is comparatively unimportant, and may be in-

jurious at every stage of the disease (§ 673). 990, d. But the treatment of apoplexy has been less the fault of hypotheses than an unsuitable application of bloodletting; neglecting the peculiar relations which the brain sustains to other organs. and the consequent modification of their properties and functions when the brain is suddenly and violently disturbed. So far as this organ is independently concerned, whether the proximate cause of apoplexy consist in pressure from excreted blood, or simple inflammation, or venous congestion, bloodletting is clearly indicated, and, to avert an impending attack, should be applied without much reserve. But when the paroxysm ensues, it is not alone the brain which suffers in a new and peculiar manner. Every vital organ sustains a shock, and each becomes a subject for particular care. Disease is now coextensive with the system, for the powers and functions are universally deranged (§ 226, 227, no. 1, 230, 231, 480-485, 489-492, 508-511, 943, 946,) and plainly deranged by nervous influences.

990, e. Hence the importance of ascertaining, as nearly as may be, how extensively the powers of life are disturbed in each individual case, that we may not complete their extinction by precipitate treat-

ment (§ 920, 934, 937, 940, 941, 943, 944, 947-949).

990, f. The consequences, which are determined by the sudden lesion of the brain in apoplexy, will not only depend much upon the natural constitution of the individual, often upon the precise nature and seat of the lesion, and the antecedent condition of the organ, but they will be variously modified by the pre-existing state of other parts; whether the system was in a state of health at the time of the seizure, or whether important organs may have been previously diseased, and thus incur a more profound lesion after the attack, and send back upon the brain the shock they have sustained, and again receive the reverberation; and whether, also, such disease may not have developed the cerebral derangement, and remain a powerful aggravating cause (§ 514, h, &c.).

990, g. The variety of lesion sustained by the properties of life, in apoplexy, is denoted by the symptoms, and the symptoms only. The pulse of an athletic subject may become, as in cases of concussion, almost insensible at the moment of the attack; while that of the feeble may acquire a volume and force exceeding its natural state. The general circulation is roused at one time, and prostrated at another

The nervous power has now the effect of an excitant upon the system, and again it is a deadly sedative (§ 226, 476, &c.). In one patient, the pulse falls suddenly to forty strokes in a minute, while in another it is as suddenly raised to more than a hundred. In one, it beats with staid regularity; in another, it intermits; in another, it hobbles; and in a fourth, it rises and falls in volume in coincidence with the prolonged acts of respiration. There is nothing uniform about it.

990, h. It need not be said how profoundly the stomach is affected, how variously respiration, how differently the voluntary muscles, the sphincters, &c., suffer (§ 476, &c.), all referable to the nervous power.

990, i. Considering, therefore, the varied influences of the brain upon the properties of life in apoplectic affections, and the manner in which we have seen that bloodletting affects this organ, and the consequent impressions which are propagated from it over the whole system it must be obvious, where the general lesion is very profound, that the abstraction of blood at the onset of the attack may so increase the pernicious influence of the brain upon the sinking powers of the system that neither nature nor art can repair the injury. This will be especially true of such cases if we bleed to syncope (§ 940, 941). But the abstraction of blood is powerfully felt, in a direct manner, by the vital properties of every organ; and where these powers are excessively depressed by the nervous influence, and that influence constantly maintained by the peculiar condition of the brain, it will happen, in the foregoing cases, that there will be no ultimate recoil from the depressing effect inflicted by the loss of blood. Here will be also another shock added to the direct injury from loss of blood, since the violence thus inflicted upon the system at large will be extended, by sympathy, to the brain; while this organ will reflect every pernicious impression it receives from others (§ 1056).—See p. 298, § 476½ h.

990, k. It should be also considered that effusion probably exists within the brain, and that bloodletting cannot reach this part of the exciting cause; that the effect of the effusion, although it be diminished, must continue for an indefinite time, and that if we lessen too much the energies of the system, they will at last fail from its increasing influence. While, therefore, we strive to arrest one evil there

should be an equal care not to increase another.

990, l. The importance of bloodletting will depend, also, upon the nature of the fluid effused; of which we may, perhaps, form some conjecture from the antecedent history of the case. In serous apoplexy, the cerebral congestion, or inflammation, is generally, from the beginning, in a low state, and is probably much subdued by the effusion. It may be, therefore, chiefly the immediate object of bloodletting to diminish the impulse of the circulation upon the brain, and, perhaps, to lessen a state of congestion in the abdominal organs that may continue to operate upon the brain. Serous apoplexy, however, is not common. Dr. Cheyne and others consider the ratio of the sanguineous to the serous as 98 to 100.

990, m. In the sanguineous apoplexy we have a more or less different state of things, and other objects are presented for consideration, than in the serous form. We have, then, not only to lessen the impulse of blood, and to strike at any remote predisposing congestions, but we must, as speedily as possible, reduce the congested state of the cerebral veins, and thus arrest the progress of the hemorrhage,

and re-establish the natural circulation and healthy functions of the brain.

But the moment when bloodletting may be applied with advantage, and the extent of the remedy, must be directed as much, or more, by the existing state of the general symptoms as by any pathological condition that may have led to the paroxysm (\S 150, 151, 990 c).

990, n. It behooves the physician to meet every case of apoplexy with entire self-possession, and to consider that no subject requires the exercise of greater skill, and, perhaps, of firmness. It is often now as with the surgeon when he is summoned to some embarrassing operation, and in the right performance of which the life of the subject is immediately concerned. The authority of custom, sanctioned by the most acute and renowned observers, will be likely to embarrass our judgment, paralyze our independence, and hold us spell-bound, when all may be depending on the unbiased dictates of the understanding. The difference of an hour in the application of bloodletting may be for the weal or the woe of the patient. Shall we deliberate? Professional reputation may be in peril; but the greater will be the reward to a sensitive and enlightened mind. Where art can be of any advantage there will be always time for calm investigation of doubtful cases. Such are the recuperative powers of nature they will generally struggle for a time with success; at least in cases where art can be instrumental. "It is probable," says Heberden, "that far the greatest part of paralytic and apoplectic patients would recover some degree of life and strength by the unassisted efforts of nature." It is this partial recovery which we should await, in certain cases, before resorting to the abstraction of blood. If Nature be too much struck down by the blow for an independent effort, we shall hardly contribute any useful succor by inflicting another. If, also, the powers of life be greatly prostrated, action is, of course, in a languid state. Whatever disease may exist in the brain is, for the present, controlled by the same principle. Hemorrhage is suspended; and the functions, every where, whether natural or morbid, are nearly at a stand. It is here, in the severest cases, in respect to the general condition of life, as it is in concussions of the brain; when, it is said by Mr. Abernethy, "it would appear in the first stage that very little can be done." This has now become the doctrine of surgeons.

990, o. When bloodletting is of doubtful expediency in apoplexy, and this is commonly only soon after the seizure in cases that admit of relief, the abstraction of blood should advance slowly, and its influence be carefully observed (§ 937). The result from a small quantity of blood may be such a relief to the brain that the pernicious influence of the organ may be so withdrawn from the system that the remedy may be soon repeated, and to a greater extent (§ 961, d).

990, p. Having brought the system, in bad forms of the disease, out of its alarming prostration, either by moderate stimulation, or cautious bloodletting, or, what is generally better, by intrusting it to its own resources, it will become important to estimate the probable extent of disease in the brain and other organs. And here I cannot but repeat the important fact that sanguineous effusions are generally the result of disease, and that they very rarely depend, even within the cranium, upon any primary rupture of blood-vessels. Dissections prove

that this condition, in almost all cases of sanguineous apoplexy, is attended by venous congestion. This view of the pathology, while it is entirely more inauspicious to the hopes of the patient than that which regards the effusion as the simple result of a ruptured vessel, requires more energetic means of treatment than the latter. Indeed, were simple rupture the source of the effusion I see not in what respect art is likely to be instrumental. It cannot be, as is commonly supposed, by diminishing the force of the circulation that we obtain much ascendency over the complaint. Indeed, in many cases, where the pulse is prostrated, relief is effected while the energy of the heart rises under the influence of the lancet. The philosophy of the effects of this remedy relates mainly to its impression upon the organic properties of the capillary vessels, directly and by reflex nervous action.

990, q. We may conclude, then, that with all the advantages of the most enlightened pathology, and the most appropriate treatment, the apoplectic must, generally, exist for a long time in a perilous condition. In the early stages, a formidable state of morbid action is to be overcome by energetic measures, whose timely application is more surrounded by difficulties than in any other disease. The brain, too, in the cases supposed, has sustained a fearful laceration, and a concrete effusion of blood is probably compressing and irritating the whole organ, and which can, at best, but slowly undergo absorption. In sanguineous apoplexy there is also an increased liability to repeated at-

tacks of the congestion and consequent effusion of blood.

990, r. It has not been my object to speak of cases that obviously admit of immediate bloodletting. These are common, and may demand an extensive application of the remedy. But the only rule that can be assigned in regard to the quantity of blood that should be abstracted will probably be found in the foregoing considerations.

990, s. In estimating the effects of cerebral disease on the system, we must duly consider the various relations of the brain to other parts. Considered simply as an organ, it is liable to the same modes of disease as other organs, and to the same relative sympathies as exist among other parts. But this is a small part of the important relations of the brain. It is especially destined to preside over the great functions of the body, however they may be the result of powers that exist and act in independence of the brain; and whenever its organic functions become diseased, these specific relations to the system are affected in consequence (§ 455, 456). This complex derangement, in apoplectic affections, will produce the most varied results; and, according to the influences of the brain upon other parts, and their reaction upon the brain, will be the endless variety of phenomena.

990½, a. In conclusion of the foregoing subject I may finally say, that, from what has been here presented relative to the nervous power, and from the extensive researches of a more critical nature in preceding sections, it appears that the nervous power is peculiar to animals; that it is a vital stimulus, sui generis; that its important office is to subserve the function of sympathy, and to impress upon the organic products some very special vital conditions; that its only participation in the function of motion is that of acting upon the organic property, mobility, through its primary operation upon irritability; that it is extremely susceptible of influences from the operation of external and internal causes, mental, vital, and physical; that these influences result in preternatural developments and various modifications of the nervous power, under the influence of its own nature, but corresponding, also, with the nature of the remote causes, respectively; that it is then reflected with a special alterative effect upon remote parts, according to their existing susceptibilities, and according, also, to the nature of the causes by which it is developed or modified, whether by the will, mental emotions, or by organic or physical causes, and that the motor channels which are elected for its remote effects are, apparently, independent of the order of the distribution of nerves; that, when thus reflected, it maintains, in one case, the harmonious action of organs, or disturbs that harmony in another, or induces disease in another, or becomes a curative agent in another; according to the nature of the influences which may be exerted upon it.

990½, b. Now, therefore, in view of all these things, as well as of what has been hitherto said of the functions of organic life, and of the consequences which have befallen the philosophy and the practice of medicine from the prevalence of the chemical, physical, and humoral doctrines of life, disease, and therapeutics, it is evident that there is nothing of greater importance in medicine than a proper understanding of the attributes of the nervous power, and that it must be regarded merely in the light of a vital stimulus, or a vital depressant, or a vital alterative, and that it has no other participation in the actions and results of animal and organic life ($\sqrt[6]{227}$, $\sqrt[4]{5}$, $\sqrt[5]{2}$, $\sqrt[4]{4}$, no. $\sqrt[6]{647}$.

I have, finally, reserved for this place another demonstrative proof that the nervous power is in no other than the foregoing sense the cause of a single phenomenon in organic beings, and that, therefore, all the causes which bring it into operation, or otherwise affect its pronunciations, exert their influences directly upon the power itself, and that an irresistible analogy is thus brought to concur with the many specific facts in proof of the direct operation of all other vital agents upon the properties of life which are common to plants and animals, and not upon the physical structure (§ 189). I say, then, that, since the nervous system is carried into all parts of the organization of animals, but has no existence in plants, and since both animals and plants possess organic functions in common, and since, also, the organic functions of animals are variously affected through the instrumentality of the nervous system, not only by causes operating directly upon the nervous centres and the trunks of nerves, but indirectly through the circuitous route of the sensitive and motor systems of nerves, and, especially, farther, since there is no anatomical union whatever between the extreme fibres of the sensitive and motor nerves, nor between them and the fibres or ultimate parts of any other tissue, it follows as a physical necessity that the organic properties and functions can be influenced through the nervous system only by a real substantive agent which is entirely different from the physical structure itself, and which is capable of extending its influences from one tissue to another between which there is no physical union, and that, therefore, all the primary essential impressions must be exerted directly upon the agent itself. Whence, also, it follows, that all the results which ensue in other tissues, as consequences of the transmission of the nervous influence from the expanded nerves to those tissues, are due to primary impressions by the nervous power upon the organic properties of such tissues, through the medium of the complex structure. Lastly, it necessarily results from the foregoing demonstration, that the organic properties appertain just as much to a real substantive agent, and are as different from the physical structure, as the nervous power is different.

The foregoing facts and arguments relative to the disconnected state of the nervous and other tissues are equally true of all the tissues respectively, and as true, also, of the organic properties as of the nervous power in the aspect of the anatomical facts (§ 168-185, 190-192, 200, 208, 215, 217, 219, 220, 226, 228, 230, 233, 233\frac{3}{4}, 234 c, d, e, f, 500, 1040, 1056). The soul offers a conclusive analogy (§ 175 b).

 $990\frac{1}{2}$, c. Nevertheless, if the physical fact, even as to the sensitive and motor nerves, were not demonstrably true, it would in no respect affect the laws, since those of all vital functions are deduced from the phenomena (§ 466); not, as with physical optics, from the mechanism (§ 131).

The Experience and Opinions of Distinguished Physicians as to Blood-letting in Inflammatory, Congestive, and Febrile Diseases.

991, a. It would not be appropriate to this work to set forth the vast range of experience in favor of blood-letting in the treatment of inflammatory, congestive, and febrile diseases, which I have explored in the Medical and Physiological Commentaries, and as contributed by men whose genius, observation, and success, will command the admiration of ages. But great controverted questions call for something more than opinions, however great the authority, or however those opinions may imply all the requisite experience. Unless excepted, I refer to the early stages of disease (§ 557 a, 869).

991, b. Bampfield introduces his remarks by saying, very justly, that, "In medical science, all reasoning and hypothesis must yield to the results of experience, and deductions from facts. I have employed venesection," he adds, "not only in dysentery, but other internal and external inflammatory complaints in the East and West Indies, with the most happy results. And is it not our sheet-anchor, our principal remedy, in the cure of yellow fever, when had recourse to within the

first eighteen hours of the attack?"

Mr. Bampfield exposes the origin and fallacy of the objections that have been made against bloodletting. He "has been astonished and shocked to find bloodletting in hot climates condemned;"—while others, of the temperate climates, think it only adapted to the tropics, or

condemn it universally.—Notes Ff p. 1135, Gg p. 1138.

992, a. Let us consider, next, the solemn statements of one who is known as the "Ulysses of Medicine," from his vast practical opportunities in numerous climates, as Surgeon-general of the British Army; and let us observe how his experience illustrates and confirms the great principles relative to bloodletting, and the universality of those principles, and their practical application under all circumstances of climate. It should be premised, however, that I have rarely found the heroic practice of Jackson necessary or expedient in its largest extent; and should be inclined to attribute more to the modifying influences of climate in the following cases, were it not that his practice was remarkably distinguished for its decision and success in various parts of the globe, while it is sustained by many of the best observers in every variety of climate. Thus, then, Robert Jackson:

"The end is not attained in many cases, particularly in the more concentrated forms of fever that appear among the military in tropi-

cal climates, at a less expense than eighty or ninety ounces of blood drawn at once." After stating, in another place, that the quantity of blood abstracted in fever, at one time, during the years 1813 and 1814, at the Hospital of the Royal Artillery, was rarely less than three pounds, frequently four or five, and sometimes six pounds, Dr. Jackson remarks that such quantities taken at once "may appear unsafe to some readers. But I am warranted to say, from a retrospect of the whole proceeding, that no accident occurred in any instance from the most excessive bleedings that were made; and I may add, that the strength was so little impaired by this apparently revolting practice, that the greater number of persons, who were treated in this manner, returned to their duty within a fortnight, in the full vigor of health" (§ 1019, d). Such, also, was Jackson's practice in other countries (§ 973 b).

992, b. Let us also hear Jackson upon the specific point of cerebral inflammation, which demands, as I have said, more than any other

disease, a fearless and extensive use of the lancet (§ 974).

"The quantity of blood," says Jackson, "which may be abstracted in cerebral inflammation, without even compromising the safety of the patient's life, exceeds a measure which, were my experience of the fact not clearly ascertained, I should not venture to lay before the public. Four pounds, taken away at one time, may be considered a moderate bleeding in the more concentrated forms; six pounds have been taken on several occasions, and a hundred and twelve ounces at a single bleeding in some. The practice, so formidable in appearance, implied no danger. It saved life by direct effect (§ 938 b, 955, 1019 d). The practice is reasonable in theory (§ 924–934, 942, 944, 948, 949). It is proved in experience to be founded in truth. The quantity, moreover, is to be measured by the effect which arises under the abstraction, not by an opinion formed under the presumption of what may be right."

In some cases of fever attended by cerebral inflammation Jackson sometimes abstracted a hundred and sixty ounces of blood, or ten pounds (avoirdupois), in a day; and he remarks in connection with this statement, that, "instead of danger at the time, or debility as a consequence of such extraordinary depletion, fainting did not always occur, and the patient, in most cases, returned to his duty within eight

days" (§ 974, 1068 c).—Notes Ff p. 1135, HH p. 1138.

992, c. In the foregoing (§ 992, b), as in the concentrated forms of fever (§ 992, a), we have a clear exemplification of what I have taught as to the tendency of inflammation to maintain the system against the depressing influence of loss of blood, and that when the brain is the seat of inflammation an exciting nervous influence is more powerfully developed, and operates with greater force upon the diseased state of the organ, and upon the heart and whole capillary system, than a similar affection of any other part (§ 480-483, 971-974).

Secondly,—"The quantity," says Jackson, "is to be measured by the effect which arises under the act of abstraction, not by an opinion formed under a presumption of what may be right. Whatever be the quantity, it is the effect produced which constitutes the RULE for guiding the measure." I have thus repeated this doctrine, for it is the most important that can be found in the annals of medicine. This rule is universal, and it is for this reason that the best practitioners never sug-

gest the *quantity* of blood which should be abstracted in any given form or case of disease.

Thirdly,—"Instead of debility, as a consequence of such extraordinary depletion," says Jackson, "fainting did not always occur; and the patient, in most cases, returned to his (military) duty within eight

days, in the full vigor of health" (§ 1019, d).

What an admirable illustration is this of the fallacy of the temporizing practice, or the more sad effects of the stimulant treatment! How forcibly it evinces the importance of making a decisive impression, at one blow, in all grave inflammations! How truly does all this proclaim the existence of peculiar properties of life, in whose alteration the essence of disease consists, and whose restoration is effected by the direct impression upon them of loss of blood! How forcibly does it refute the humoral pathology, and that not less erroneous assumption that disease is constituted by some positive change or structure, or the yet more glaring fallacy that it consists in debility!

792, d. I have said that it has not often fallen to my lot to carry out Jackson's practice, excepting in principle (§ 992, a). This may be owing, in part, at least, to the fact of having commonly enjoyed the opportunity of applying remedies at the early stages of disease. Where I have found the full extent necessary, it has been mostly among children; estimating the ratio of the loss according to the relative ages and size. The most remarkable example has occurred in the case of my only child; whose general history of health is stated

in the Commentaries for another purpose (vol. i., p. 693).

Not long after his very protracted disease had given way, and being at the age of nine years, he was suddenly and violently attacked with well-marked inflammation of the brain, lungs, and small intestine. I raised him to an erect posture, and bled him till syncope came on. The symptoms gave way; but, in six hours afterward, those of the brain, and, in an inferior degree, of the lungs and intestine, had reappeared. I then bled him again, in the same posture, and to the extent of syncope. Before exhibiting any medicine, I still awaited the ultimate effect of the loss of blood. The cerebral symptoms gradually presented themselves again, and I bled him, for the third time, as before, at the expiration of about twelve hours after the second bloodletting. Soon afterward, I gave him one tea-spoonful of castor oil, which completed the direct course of treatment. In two days after the last bloodletting, I took him upon the rail-road a distance of five miles, and returned (§ 955 b, 958 a). It may be worth adding, in connection with my former statements relative to his extreme infirmity of health during the first seven years of his life, that he has enjoyed a very robust constitution since the illness described in this section; being now seventeen years of age (§ 870 aa, 892 i, 974, 1068).

The quantity of blood abstracted in the foregoing case was very large at each abstraction, and exceeded, in the ratio of the age and size of the subject, what I shall have recorded of the experience of

others.

993. The experience of Moseley corresponds with that of Jackson, and where the remedy had been apparently of ample extent, he remarks that, "it has frequently happened in the fever of the West Indies, that accidental bleeding from the orifice when the patient had

fallen asleep, to far greater quantities than has ever been directed to be taken away, has carried off the fever entirely, and the surprise on discovering a profusion of blood in the bed has been changed to joy for the alteration produced in the patient" (\S 973, b).

There are few practitioners of much experience who have not wit-

nessed similar events (§ 1019, e).

994, a. And how well is all this sustained by Dr. Rush, who has "always observed that the cure of a malignant fever is most complete, and the convalescence most rapid, when the bleeding has been continued until a paleness is induced in the face, and until the patient is able to sit up without being fainty." "Bleeding," he adds, "should be repeated while the symptoms, which first indicated it, continue, should it be until four fifths of the blood contained in the body are taken away;"—being conformable to the precept of Celsus, that

"We must not run from one remedy to another, so long as that remains which was there at first" (§ 1007);—or, as Porter has it, "it is not sufficient to diminish an increased action, unless the constitution be kept, until the period of danger is over, in a condition that will render

a renewal of that action unlikely to occur" (§ 954, b).

994, b. The same result of an almost unsurpassed experience is again and again reiterated by Rush. "The half-way practice of moderate bleeding," he says, "has kept up the mortality of pestilential fevers in all ages and in all countries. It is much better not to bleed at all than to draw blood disproportioned in quantity to the violence of the fever (§ 960, b). Bleeding must not be discontinued so long as the symptoms which first denoted its necessity continue."

In very prostrating forms of fever, he says, that "bloodletting lessened the sensible debility of the system. Hence patients frequently rose from their bed, and walked across the room, a few hours after the

operation" (§ 569 e, 898, 992).—Note Ff p. 1135.

995. And so, also, Armstrong: "In pneumonia," he says, "bleed your patient to approaching syncope; otherwise, instead of benefiting

him, you will do him harm" (§ 960, b).

And again: "In inflammations of the serous membranes, or of the parenchymata, I bleed," he says, "more decidedly than I ever did." "I have treated nearly three hundred cases of severe *enteritis* with bleeding, &c., and with a success far greater than I have heard from any other plan. There is no success on record at all comparable with it" (§ 1005, e, i).

996. And so Mr. Lawrence, who says, that,

"In cases of inflammation, where the blood comes freely out of the vein, I generally let it run on till it stops; for that seems to me the only way of doing good" (§ 960).

997, a Wardrop, in his excellent work on Bloodletting, lays down

the same rule and the same experience. Thus:

"When a large quantity of blood is not taken away at the first bleeding, in inflammation, or at a second depletion quickly succeeding, I have generally found that, on all future occasions, it is seldom practicable to abstract any considerable quantity, however necessary it may appear; and thus it is, that when copious bleedings are not employed at the commencement of the treatment of inflammatory diseases, and if the patient afterward recover, it has generally been-from the employment of a great number of bleedings. Moreover, it is only

in such cases wherein the pernicious effects of bleeding are exemplified" (§ 950). "There seems always," he says, "to be a disposition in patients, as well as in medical men, to economize blood" (§ 960, 1007 b).

997, b. It is an aphorism with Gregory, that, in severe inflammations and fevers, "the danger of a large bleeding is less than the dan-

ger of the disease."

998. "With gangrene, infarction, and abscesses in prospect," says Beddoes, "transient syncope, from loss of blood, is a slight evil. The rule, that the constitution recovers much more kindly from debility by bloodletting than by disease, affords great encouragement" (§ 569, 1007 b). "Numerous facts show that in high inflammations the lancet can scarce be used too freely."

999, a. Jackson says that "Dr. Rush carried subtraction of blood to a great extent in yellow fever; but the quantity subtracted was obtained by repeated subtractions, not by abstraction at one time. The mode of depletion was not abrupt, such as arrests disease by force, and such as I have in view in the present history" (§ 929-934, 938 b,

942, 944, 948, 949, 955).

999, b. It may be true that Dr. Rush sometimes fell short of the proper effect. It may be true that his moral courage was unequal to that of his great cotemporary, since each was extensively denounced as "a murderer;" and Rush could hardly fail of being sometimes embarrassed by his strange delusion that "debility is the universal predisposing cause of disease." Nevertheless, a glance at a preceding section (§ 994) will assure us that the general charge is without foundation. His philosophical acumen led him to bleed extensively, and with success, in many cases where there appeared no hope to others but in powerful stimulation. There is also a distinction to be made between the yellow fever of Philadelphia, and that which called forth the heroic practice of Dr. Jackson. The prostration of the heart from intense sympathetic influences reflected from the vessels engaged in the morbid processes was often greater, and there was less active inflammation to sustain decisive bloodletting, and more of venous congestion to diminish the tolerance of loss of blood, and to impart malignancy to fever, in the former, than in the latter instance. Nature, therefore, frequently interposed an obstacle which compelled the American philosopher to be sometimes content with small and repeated abstractions of blood (§ 974, 975, 977, 983, 985).—Note Ff p. 1135.

999, c. The foregoing reference to Rush's doctrine of "debility" (§ 999, b) leads me to an extension of a preceding section, where I have explained the acceptation in which I employ the term prostration (§ 961, b), and which goes with former sections in elucidating the nature of that condition which is commonly mistaken for "debility" (§ 487 h, 569). What I now purpose saying is, that the condition of the heart takes a very large share in those morbid demonstrations which have led to so many theoretical and practical errors. But, the heart, in these cases, is mostly obedient to disturbing influences propagated upon it by the instruments which are carrying on the morbid processes, and where the powers may exist in a very exalted, though, also, otherwise modified, state. Those extreme vessels, however, determine upon the heart a prostrating nervous influence, and often, also, an accumulation of blood about its right cavities, which contributes yet farther to the embarrassment of the organ. This will be readily ap-

preciated from what has been variously said upon relative topics in former sections; but the whole principle may be seen by referring to the instrumentality of the nervous power in the operation of loss of blood; while, also, the philosophy which is there set forth borrows a corresponding illustration from the subject embraced in this section

(§ 916–922, 929–938, 942–949, 500 m, $687\frac{1}{2}$ –689, $694\frac{3}{4}$).

The heart, being prostrated in the foregoing manner, increases, by reflex nervous actions, the morbid state of the instruments of disease, complicates all the phenomena, and does its large part in leading all but those who will take the trouble to investigate the philosophy of life, and analyze the symptoms of disease, and apply them critically, according to the share which belongs to each tissue and organ, to rest their intellectual efforts upon the symptoms alone, and their hopes in tonics and stimulants. But, he who will penetrate this seeming labyrinth, yet accessible to all, will discover, at once, that the remedies should be addressed to the immediate instruments of disease, and that whatever will bring relief to these will certainly relieve the heart, and dissipate the phantom, debility; while, on the other hand, every cause that may increase that pathological state of the instruments which are the absolute seat of difficulty and danger, will as surely engender, sooner or later, increasing embarrassment of the heart, and a consequent multiplication of the morbific influences which radiate from the centre of the circulation (§ 892 c, 965 b, 966-968, 500 m).—Nole I.

1000. Few medical philosophers have done so much for therapeutics as Sydenham; and with his name is associated one of those great revolutions in practice in which bloodletting is the foremost remedy. There was then, as now, that timid caution which has contributed so largely to the common prejudice against the abstraction of blood.

"Nothing," he says, "is more frequently urged as a capital argument by those who condemn bleeding, than the mischief which arises from bleeding in an improper manner" (§ 892 a, 892¼ c, 960 a, 1005).

1001, a. The "improper manner" to which Sydenham refers (§

1000) is justly, however forcibly, expressed by Botallus. Thus:

"Bleeding does no service in many cases, either because persons have recourse to it too late, or use it too sparingly, or commit some error in both these particulars. But, if our fears be so great, and we take away so small a quantity of blood, how is it possible to judge what good or mischief bleeding may do? For, if a disease which requires the loss of four pounds of blood for its cure, and yet but one be taken away, destroy the patient, it does not therefore prove destructive because bleeding was used, but because it was employed in an improper manner (§ 950, 965 b). But ill-designing and indolent men endeavor to lay the fault to the bloodletting; not because it did really do mischief (otherwise than by its improper use), but because they desire to give every body an ill opinion of it. Or, suppose they do not do it from wickedness, they cannot be excused from ignorance and perverseness." It is also his opinion that "one hundred thousand men perish from the want of bloodletting, or from its not being timely employed, where one perishes from excessive bloodletting, when practiced by a physician" (§ 1005).—Note p. 729.

1001, b. Botallus was critically right in qualifying his remark by adding, "when practiced by a physician." No little of the prejudice which rational medicine encounters arises from the former indis-

creet use of the lancet, in the hands of the surgeon, immediately after concussions from falls, &c. The sad experience of some of the most able has led to admonitions like that which is recorded in a for-

mer section (§ 960 a, page 720; § 1007, b).

But shall physicians deliberate when inflammation is careering in the great organs of life? Can there be a question of the applicability of bloodletting to phrenitis, pleuritis, peritonitis, pneumonia, and to many other grave inflammations, under their ordinary circumstances? It is true, we have lately seen practitioners, Dr. Dickson, for example, boasting of their success without having "ever wetted a lancet." But I do not believe that this exclusive practice has many open advocates; and to admit its imputed results would be to renounce the dictates of our own and of common observation. A more limited opposition, however, to bloodletting in grave inflammations is making an inroad upon former experience; nor is it the least remarkable circumstance that it enlists the most able disciples of the anatomical school. And although they may often admit the utility of the remedy in a general sense, when they come to its practical application to particular diseases, we are told that it is either useless, or prejudicial (§ 960). [The "stimulating plan" is now in vogue, 1860.—Note, p. 872].

1002, a. But once more, as to the prostrating forms of fever, from which it will farther appear that neither the yellow fever, nor others of an analogous character, have been so modified by climate, seasons, &c., as to preclude the abstraction of blood; and that if loss of blood be demanded by simple inflammation, it is much more so when inflammations are complicated with idiopathic fever, and especially when that fever is of a "malignant nature," and constantly imparting its

malign influence to the local developments (§ 999, b).

Dr. Stevens, of the West Indies, the celebrated advocate of the saline treatment of fevers, affirms, in his late work on the Blood, that, "Those who were well bled, in the yellow fever, and properly evacuated in the beginning, almost invariably recovered." "He took blood till he had nothing to fear from increased action." I have introduced this statement for the purpose, also, of showing that the credit which he imputes to the saline treatment of yellow fever is wholly due to the decisive bleeding and purging which he adopted. The saline practice in fevers was pretty largely in vogue some centuries ago, and has been lately brought forward to give plausibility to the humoral doctrines.

1002, b. Mr. Evans recently states, that in the Indies "we bleed largely in the yellow fever, repeating the operation in two hours if there remain the slightest pain on pressing the epigastrium; and, in general, if any gastric affection remain after the second bleeding, toward the close of twenty-four hours, we repeat it a third time, and

apply the leeches afterward."

This practice, as I learned on a visit at different islands a few years ago, prevails throughout the West Indies; and, in Eastern India, it is well known that bloodletting was never in higher repute in

all congestive fevers than at the present day.

1002, c. Baker remarks, that it is necessary to abstract, by repeated bleedings, twelve or more pounds of blood in the malignant fevers of Brazil. The distinguished Hillary urges free bloodletting on the first and second days of yellow fever, and in the worst forms of the disease.

1002, d. "Here is a case," says Mills, "of the typhus gravior of Cullen, or such as is commonly denominated putrid. The petechiæ (so much dreaded by the opponents of bloodletting) disappeared after the second bleeding; an effect I daily witness from the use of the lancet, which clearly proves that this symptom proceeds from vascular action." And so, also, Dr. Parry; who introduced the only successful or philosophical treatment, that of bloodletting, in purpura hemorrhagica; now treated by stimulants and astringents, but in vain.

1002, c. By the same process of induction from the vital phenomena that conducted Parry to the true pathology of purpura hemorrhagica, Lind, Blane, Milman, Rouppe, Fordyce, Girtanner, Pinel, Baglivi, Heberden, De Haen, Moore, Bampfield, Darwin, Beddoes, Woodall, and others, inferred the inflammatory nature of scurvy (the great pillar of humoralism), and practiced bloodletting as the first step in its treatment. Diet here illustrates the vis medicatrix (§ 853).

1002, f. What shall be said of the celebrated jail fevers, where every body now stimulates? Let us hear the illustrious Pringle, who, more than any one of the old school, taught the pathology of living putridity. He was one of the last of a long line at whose beginning stands the Roman projector of humoralism; having died in 1782, when solidism again triumphed for awhile. He was a man of vast experience, great success, and of universal renown. He was an English baronet, professor, physician-general of the British forces, and studied and treated diseases in Germany, Flanders, Scotland, London, &c. He was, in brief, like Robert Jackson, a "Ulysses in Medicine," and, like Jackson, he found that the same diseases required the same general treatment in all climates; being utterly regardless of the humoral doctrines at the bed-side of disease.

Pringle, I say, bled in all forms of fever—jail fever, typhus syncopalis, and whatever the imaginary degree of putridity. "Bleeding," he says, "in *putrid* fevers, is indispensable." "It is the first

thing to be done in the beginning of the treatment."

Riverius, an eminent French physician of the seventeenth century, like Pringle, considers "putridity a reason for bleeding at all stages of petechial fevers,"—"non ullum unde eminere periculum,"—nor did any injury result from it.

Grant says that, "even in the putrid diathesis of fevers (as he calls it), where much evacuation is required, more or less blood ought to

be taken before proceeding to other evacuations."

Baillou, in the enlightened days of humoralism, advises "bloodletting in all putrid and malignant fevers, even when there is a tendency to hemorrhage from dissolution of the blood" (§ 1002, c). And so of many other distinguished theorists in the school of putridity.

1003. Let us now regard the language of the best experience as to the treatment of a form of fevers for which "bark" is commonly supposed to be an almost unfailing specific, but which, even its alkaloids, often entails the most obstinate forms of local chronic disease, when untimely, or excessively, employed (§ 892, &c.). Thus:

"It may be laid down," says Armstrong, "as an established principle, that if venesection does not absolutely cure intermittent fevers, it paves the way for other remedies, and is, on that account, highly necessary." Or, as Hippocrates has it, "he who would purge bodies, must first make them permeable." Baglivi, Torti, and other distintions are seen to be some the permeable of the seen to be some the seen to be seen the seen to be seen t

guished Italian physicians, affirm, positively, that the local complications of their intermittents could not be cured without bloodletting. Sir John Pringle, in treating the intermittents, mild or malignant, in "low, marshy countries, found it necessary to begin with opening a vein, and to repeat the operation according to the urgency of the symptoms." "A person," he says, "unacquainted with the nature of this disease, and attending chiefly to the paroxysms and remissions, would be apt to omit this evacuation, and to give bark prematurely." This is what led Cleghorn into his fatal mistake (§ 1005, h). But we ultimately hear from him, that, "for his part, when called early enough, he used to take away some blood from all people, of all ages, when affected with tertians, unless there was a strong contra-indication." And so Senac: "the physicians bleeding five or six times in an epidemic tertian." Cragie says, that, in Great Britain, remittents require the loss of twenty-five to thirty ounces of blood (§ 960, a).

1004, a. It would be superfluous to extend the foregoing species of testimony afforded by modern practitioners in favor of bloodletting in the treatment of inflammatory, congestive, and febrile diseases. In the article on Bloodletting, embraced in the Medical and Physiological Commentaries, I have presented the experience of all the distinguished practitioners from the earliest ages of philosophical medicine, and it may be there seen that without exception they have concurred in their testimony as to the transcendent utility of blood-letting.

1004, b. The "father," himself, says, that, "in all active inflammations we should open a vein, and if the disease be vehement and prostrating, the loss of blood will bring strength to them that lose it,— 'robur ipsis affuerit.'" He abstracted blood for the relief of those syncopes which attend the worst forms of congestive typhus; as did, also, Galen, Celsus, Aretæus, Trallian, Paul, Aurelian, Avicenna, &c.

1004, c. Oribasius, about three hundred years after Christ, states that he was bled to the extent of two pounds for an attack of the plague, and that his reliance was mainly upon this remedy. Galen bled largely in this disease, and he is the first who records the quantity. "I remember," he says, "to have taken away in some instances, at one bleeding, six pounds of blood, which immediately extinguished the fever, nor was there any loss of strength in consequence" (§ 992). Such was his success by this mode of treatment, that the spectators exclaimed, εσφαξας, ανθρωπε, τον πυρετον;—" Oh! man, thou hast cut the throat of the distemper."* Avicenna says that he has sometimes abstracted, in the plague and "putrid fevers," at one bleeding, five or six pounds of blood,—"quinque aut sex sanguinis libra auferantur" (§ 1019, d.) Bleeding largely in the plague was a general practice after the revival of learning, and was practiced through the 16th, 17th, and 18th centuries; as it was, also, in other fevers, and in inflammatory and congestive affections. The exigencies of the disease was the criterion as to the quantity of blood to be abstracted. Septalius states that it was the universal custom of physicians to bleed in the plague of 1575 and 1576. "Communi consensu in hujusmodi nobile remedium nullo modo pretermittendum esse decreverant." And so Riverius, of a similar epidemic, "Deo sit laus et honos! quotquot hoc tractati sunt modo feliciter evaserunt!" In later times, Faulkner commends bloodletting in the plague, and says that "when the blood was in a dissolved state, the remedy was not less

^{*} Galen's success so raised the hostility of the Roman physicians as to banish him from Rome for several years; they denouncing the remedy, and he immortalizing them.

favorable." Assalini remarks that, "At the commencement of the plague, I saw the necessity of making use of bleeding in proportion

to the strength of the patients."—Note Ff p. 1135.

And, as to the less prostrating forms of fever and inflammation, Baglivi supplies an example of the general practice in the 16th, 17th and 18th centuries. He observes, "Omnes acutas et inflammatorias febres, hic Romæ, curare incipio per sanguinis missionem." And so of all the eminent Roman physicians down to the recent day of Rasori.

1004, d. It has been often thought remarkable that Hippocrates had never designated the quantity of blood which may be demanded by any given form of disease. The reason is, he was too much of a philosopher. He knew that no rule, in this respect, would be useful; but, on the contrary, unwarranted by nature, and liable to the worst results. Look at his writings, and you will find him bleeding according to the symptoms, and the general history of the case. This, in deed, he often says, was his rule. He had no other in relation to

quantity.

1005, a. Before leaving these practical considerations it may be well to listen to the confessions of a disastrous experience which befell some of the most enlightened of our profession from their neglect or misapplication of bloodletting. Let us select examples of prostrating forms of disease, where it too commonly happens that its nature and exigencies are misapprehended, or imperfectly understood, and where "debility" is regarded as the essential pathology, and is supposed to demand the stimulant plan of treatment. These examples will cover the whole ground, and disarm the stoutest prejudice in other less ter-

rific forms of prostrated strength.

1005, b. The distinguished Mr. Hey shall speak first, and of those cases of puerperal fever in which "debility" presents its most appalling aspects. This able man had unhappily treated the disease either with tonics and stimulants, or with inadequate bloodletting. He finally introduces a case (his ninth case), which was the last in which Mr. Hey employed the bark and wine, or procrastinating, treatment. It was the last mistaken act that divided the professional life of Mr. Hey into two distinct eras. The patient died, and with her death came his full conviction of his error. "If the disease," he says, "is clearly ascertained, no other consideration is of much importance. The state of the pulse affords little information, either as to the propriety of bleeding, or the quantity of blood to be taken away; and if we are deterred either by the apparent weakness of the patient, by the feebleness and frequency of the pulse, or by any other symptom, from bleeding copiously, we shall generally fail to cure the patient."

1005, c. And now mark another maxim of this able man, who felt his way to truth over many a victim of malpractice; and what he says of puerperal fever is equally applicable to all other fevers when complicated with inflammation or venous congestion. "There is a vast difference," he says, "in the puerperal fever at different times, and in different situations and circumstances. In some cases it appears like a phlegmonous inflammation; in others it destroys with more rapidity and certainty than the plague. But, the means of cure are precisely the same in both; but in the worst forms the measure of bloodletting is greater and less limited, and the period within which it must be employed is far more circumscribed." "The truth is," he says

(still lamenting his mistakes), "that bloodletting has seldom been fairly tried. Either the quantity of blood taken away has been too small, or the time when it was taken too late for any use; and thus the principal remedy for the disease has been brought into disrepute" (§ 965 b, 1000, 1001.—Also, § 500 m, $694\frac{3}{4}$, showing the import of the pulse).

1000, 1001.—Also, § 500 m, 694\frac{3}{4}, showing the import of the pulse).

1005, d. But Mr. Hey was mistaken as to the novelty of the practice. Like many others, he depended too much upon his own genius and experience; neglecting the past, and thinking that medicine is the work of a day. Hence his ignorance of the labors and of the choice experience of his predecessors. Bloodletting had predominated, as the only great remedial agent for all inflammatory affections and fevers of the most depressing character, ages before Mr. Hey came to illustrate the truth by other martyrs; and this in England, Germany, Arabia, Italy,—the island of Cos (§ 1004, b). The "disrepute" of which Mr. Hey speaks was then only local, not general; for, while the temporary reign of the "bark and wine treatment" crippled the best practitioners in Great Britain, reason and sound practice were unrestrained in other countries.—Note Ff p. 1135.

1005, e. The equally able and distinguished Mr. Gordon had the same melancholy experience with bark and wine, and the procrastinating treatment of puerperal fever; and, like Mr. Hey, he shifted his practice to early and copious abstractions of blood, and has left a record of the happy fruits of his dear-bought knowledge. He has one remark which proves the inutility or the positive injury of inadequate bloodletting. "He lost," he says, "Every patient when he bled only to the extent of ten or twelve ounces; but that ALL recovered when he had the courage to abstract twenty or thirty ounces" (§ 950, 965 b). Armstrong, by "copious bloodletting, lost only five out of forty-three cases" (For the works &c. quoted see Med. and Phys. Comm. ut cit.).

1005, f. And here is Denman, the eminent author of works on Midwifery, who, like Hey, and Gordon, had carried havoc into the chambers of puerperal women. He, too, once bowed at the fascinating "idol, Debility;" but having lost most of his patients under the seductions of this ignis fatuus, he turned himself to the Genius of philosophy, and, as a noble atonement to mankind, left behind him, like

Gordon, and Hey, a record of his errors.

"I am now convinced," he says, "by manifold experience, that my reasoning was fallacious, and my facts groundless, and that which I had considered proofs of the insufficiency, or the impropriety, of bloodletting in puerperal fever, ought, in reality, to have been attributed to the neglect of performing it in an efficient manner, and at the very beginning of the disease" (§ 1000, 1001).—Note H p. 1117.

1005, g. Leake says that, "every puerperal woman, in Lowder's time, who was blooded, died; ten ounces being considered a large bleeding;" while Leuret, accustomed to the timid practice of Lowder, affirms that, "he had never seen a woman escape after bleeding." Here it will be readily perceived that the inefficient bloodletting aggravated the disease (§ 950, 965), just as it is allowed to have done, in the same affection, by Hey, and Gordon, and Denman.

1005, h. With the familiar name of Cleghorn are associated, as in the former instances, a sound judgment and large experience. Let us consider his experience in a pestilential, prostrating, bilious pneumonia that ravaged the island of Minorca; and let us not fail of being

admonished by his example, also, of the importance of taking for our guide the lofty principles of our science, and the experience which is

taught by adversity as well as by happier auspices.

This epidemic pneumonia was complicated with idiopathic, congestive, fever, attended by "insidious intervals and treacherous remissions," and by great prostration, or "debility" (§ 569). And now mark the vacillating treatment so characteristic of weaker minds, or where ignorance of medical philosophy leads to an obstinate adherence to the suggestions of prejudice and timidity. Mark, also, the uselessness or the injury, of small abstractions of blood, and the triumph of greater (§ 950, 965, 1000, 1001).

"I attempted," says Cleghorn, "to cure the patients by bleeding once or twice a day, except during the insidious remissions; but they generally perished. This unforeseen event startled me greatly, and led me to review the whole progress of the disease," &c. He then determined "to adopt the advice of Duretus, and to use the lancet with more caution." But his failures became still more frequent and

mortifying (§ 811-815)—Note Ff p. 1135.

"At length I was convinced," he says, "that instead of too much, too little blood had been taken away in the beginning, and that I had been misled by the insidious intervals. I then began to bleed more plentifully, taking away thirty or forty ounces within the first three days of the distemper. This method succeeded well in several of the

cases" (§ 965, b).

Still he was not satisfied. "At last," he goes on, "about the middle of March, when the disease raged with the utmost fury, having found that there was the most absolute necessity for bleeding largely without delay, in order to preserve life, I began to put in practice the following method of cure, which seldom or never falled; not only in young, robust people, but even in those of more advanced age, pro-

vided I saw the sick before the end of the third day."

This "method" consisted in abstracting blood in the horizontal posture, "till the pains abated or the patient began to faint; taking from eighteen to twenty-seven ounces, avoirdupois. If the symptoms continued, a few hours afterward the same quantity was again taken away, without regarding the state of the blood, &c. Next-morning, if there were any remaining symptoms, the bleeding was repeated, and the blood carefully weighed. From fifty-four to sixty ounces were frequently taken away during the first twenty-four hours of attendance. If any symptoms returned, the patients were immediately bled again to the amount of fourteen or twenty-seven ounces."

What a contrast in treatment,—what a contrast in results! Bloodletting, decisive bloodletting, was at last almost the only remedy employed, and it now succeeded in every instance where its timid application had been, before, as universally fatal (§ 950, 954 b, 965 b, 1000 1001). But a "horizontal posture" is unfavorable and may not be safe.

And here let us not fail to observe the same results in the practice of Cleghorn as in that of Jackson and others in analogous epidemics (§ 992-999). "Under this method of treatment, it was remarkable," says Cleghorn, "to observe how rapidly the sick recovered their usual health and strength, notwithstanding the great loss of blood which they had sustained; while many, who had been bled more sparingly, continued in a languid, infirm state, for some months." Patients of the lat-

ter class were only imperfectly relieved. Congestion still remained about some of the great viscera, especially the liver, by which, also, the powers of digestion were maintained in a prostrated state. Under these circumstances, errors in diet, and mental and bodily fatigue often contribute to maintain and exasperate the consecutive derangements; till, at last, it frequently happens that a slow increase of the local diseases becomes the exciting cause of another explosion of the constitutional malady. Thus the patient not unfrequently goes on revolving, year after year, through mitigated and exasperated conditions of disease, which more decisive treatment by bloodletting, at its onset, would have prevented (§ 868, 883 b, 892 d).

I have stated the several successive steps of Cleghorn's plan, that each may be compared with the others. The quick transition from wrong to right evinces the hand of a master. The record is full of the most important instruction; and while I hold it up to the present generation, I would that not only its practical instruction, like the sad experience of Gordon, and Hey, and Denman, should be duly regarded, but equally, too, that the frankness of each should be emulated.

1005, i. Dr. Boyd, also, subsequently to Cleghorn's time, in describing the malignant fever of Minorca, states that bloodletting must be carried to the extent of positive relief, without reference to quantity. He sometimes repeated the operation four times in a day. Our inland practitioners, at the south and west of New York, will see in the congestive fever of Minorca a simile of their own as sometimes complicated with "bilious pneumonia;" while their practice responds

more or less to that of Boyd and Cleghorn.

1005, j. Erysipelas is another wide-spread and prostrating disease in its epidemic form, which has beguiled the multitude into the fatal use of "the bark and wine treatment." In his Essay on Bloodletting, Dr. Wardrop states that, "during a long attendance at a public hospital, a certain physician had never known bloodletting employed in erysipelas, and that nearly all the cases that he had seen of that disease, affecting the head and face, had terminated fatally." And so Armstrong: "The wine and bark system is of all the most fatal practice in erysipelas." "Five individuals had erysipelas in one house,

were treated with bark and wine, and all died" (§ 995).

When "erysipelas" presents itself as an epidemic, it displays its connection with a far graver form of disease in the abdominal viscera; especially hepatic congestion. And such, probably, is always its complications when sporadic only. But, the symptom is conspicuous; and hence the name, and hence, also, the usual treatment. The attention is apt to be turned, mainly, to the sympathetic inflammation of the skin. The obscurely marked, or what Cleghorn would call the "insidious," affection of the liver, &c., is not appreciated, and the force of the treatment, therefore, too often takes the wrong direction. Nothing, indeed, is more common in "epidemic erysipelas" than an absence of the cutaneous affection in the worst forms of the disease; and these very cases, from their exact resemblance in all other respects to those which are marked by the symptom, go by the same name, and get the same treatment. I have seen many instances of this nature; particularly during the late prevalence of the disease in Vermont and Newhampshire. I have seen their subjects fall victims to the disease within two and three days from the attack, where there was no inflammation

of the skin; and, in other instances, where the skin was mottled with patches of a low degree of inflammation. I found the practitioners, however, generally taking the right course, and regarding the affection of the skin as symptomatic only. But, the disease presented itself in a very grave form; and it was interesting to observe that, while it had many victims under opposite modes of treatment, the greater success of the depletive plan generally won over the few who had preferred stimulating (§ 689 l, 861, 894, mottoes, 905 $\frac{1}{2}$ b, 961 b, 964 c. Also, Med. and Physiolog. Comm., vol. ii., p. 603–607, Article Eryspelas).

1005, k. Let us consider, also, the adverse results of the stimulant, and even of the tartar emetic treatment of pneumonia (§ 892\frac{4}{5}, g). It is the opinion, for example, of Dr. Stokes, that "General bloodletting is not to be considered the chief means of removing the disease." "In the typhoid form, the best practice is to use wine in conjunction with local bleedings." "General bloodletting," he says, "is to be used with extreme caution, and the vital forces are to be carefully supported." But, "In two instances only has he seen pneumonia cut short by bleeding"! This admission appears to be conclusive against the doctrine of "saving the vital fluid," according to this distinguished writer, and especially that of "supporting the vital forces by wine" (§ 569 e,

983).—Stokes, on Diseases of the Chest, p. 226, 227, 231.

Dr. Williams, in his work on Diseases of the Chest, appears to have enjoyed as little success in the treatment of pneumonia, and for the obvious reason that he considers "local depletion the utmost that can be attempted in typhoid pneumonia. Considerable advantage may, under these circumstances, be sometimes obtained from dry cupping on the chest, which, for a time," he thinks, "tends more effectually than even bloodletting, to draw the fluids from the congested organs, while it does not waste the blood from the system" (§ 960). This philosophy has numerous admirers, who regard it, with Dr. Arnott, as "a great modern improvement in the healing art," and as one of the luminous proofs that the nineteenth century has witnessed a great revolution in medicine; or, as Louis has it, that "medicine is now in its infancy." Apropos, of this distinguished Frenchman, who is opposed, mathematically, to the abstraction of blood in pneumonia, erysipelas, "typhoid fever," and acute intestinal inflammation; with their complications, also, of other local inflammations. And so, too, of many other distinguished French physicians, who rely mainly on the watching system, or on the tartar emetic practice. But, what are the results? Chomel makes the average mortality from pneumonia, at the hospitals, one in four; Louis lost one in three; and Legarde one in three. Leconteulx reported twelve out of thirty, by the antimonial treatment. These last were treated by Laennec.

But, in these United States, where bloodletting is thoroughly practiced, the loss does not exceed one in twenty to twenty-five. There is here, however, no exclusive system, no "numerical method;" but the treatment proceeds upon Hippocratic principles. The symptoms, and various other circumstances, attending each individual case, regulate the practice. It is not all bloodletting, nor all tartarized antimony. Cathartics, calomel, blisters, &c., form as well a part of the treatment. Nor have we much knowledge of the effects of bloodletting in the advanced stages of the disease; mainly for the reason that we adopt it early (p. 517, note).*—Notes F p. 1114, Mm p. 1141.

^{*} Our large cities and hospitals, but not the country, must be now excepted (p. 872, P.S.).—1860.—Bloodletting is now every where greatly abandoned.—1867.

It is said by Dr. Osborne, in his work on Dropsical Diseases, that "Since what has been termed the tartar emetic treatment has been introduced into Great Britain, and the practice of bleeding has consequently been to some degree discouraged, it appears to me that the advanced stages and fatal terminations of pneumonia have been frequent; and in this judgment I am confirmed by records on the large scale" (§ 960, a).—See P.S. 1860, at p. 872.—Note F p. 1114.

1005, l. As to any modifying influences from climate in England, either in respect to pneumonia, or other inflammations, or all the varieties of fever, we have only to consult such authors as Armstrong, Jackson, Johnson, Wardrop, Elliotson, Lawrence, Smith, Davies, Weatherhead, &c., &c., to be convinced that those diseases are now, as ever, the same there as in America, and require the same general plan of treatment. Looking back to the age of Sydenham, and along the intermediate periods, we find that every thing, on this subject, has remained without any essential change. It is practice alone that has fluctuated. And, if we cast our recollections through the vista of time, over various countries, till we reach the age of Hippocrates, we shall still find that diseases, of a given denomination, have been the same, and have ever required the same general treatment.

 $1005\frac{1}{2}$, a. From what has been now said, under the present division of my subject, and more especially from the wide range of experience presented in the Medical and Physiological Commentaries, it appears that there is one universal consent among the great physiological practitioners as to the importance of decisive bloodletting in all forms of active inflammation, and in high grades of fever; whether it appear in the shape of the plague, of yellow fever, of typhus, or other inflammatory or congestive forms. It has been so from the earliest days of the science; in all countries, in all climates, in all constitutions, at all ages; and, whether in the Mediterranean or the Caribbean Isles, the jungles of Asia, the pestiferous regions of Africa, the paludes of Italy, or the high, and temperate, and salubrious countries of Europe and America, we witness the immutable principle that diseases and their general method of cure are every where nearly the same. Constitution, habits, and age, certainly modify the details of treatment, more or less; climate comparatively little. The great fundamental laws of disease remain without change, as do, also, the leading conditions of disease. We have all that Hippocrates described before our own eyes, and we are astonished at the identity. We think him, at one moment, a prophet; and when, at the next, we realize a simple narrative of only what he observed, we are either amazed at his sagacity and philosophy, or that we should have been so slow to have discovered the truth ourselves (§ 624, 1068).*

 $1005\frac{1}{2}$, b. The human constitution, its laws, susceptibilities, &c., are, in a general sense, every where the same; while the remote causes of disease are the same now as at the beginning of time, produce their effects upon the same properties, whose nature cannot be permanently affected (§ 180-182, 286), and whose results are connected by a chain of analogies. The pathology of inflammation, or of simple or congestive fever, therefore, is the same, respectively, in principle, at all times, and in all countries, and the great principles of treatment must also be immutable. But, modifying causes impart various shades of difference to every epidemic, to every individual case. To under-

* See Notes Fr p. 1135, GG 1138, HH 1138.

stand the complex, or even leading condition of each case, what its general nature, what peculiarities may arise from various causes, what the exact adaptation of remedies, how much the successive changes may be due to nature or to art, requires anceasing vigilance (§ 624).

1006, a. And now let me ask, whether the vast experience, and the precepts relative to bloodletting, of the able physicians who have given to medicine its rank and dignity, are to be impugned by chemists, or by the prejudice, or the limited, or the careless, observation of many physicians, who are too apt to deceive themselves into the belief that they imbody the only experience which can be available in disease, or which enlightened philosophy can approve (§ 1007, b)?

Doubtless, it will appear absurd that I should have embraced the chemists, and as foremost, too, in the preceding interrogatory. But, is it not the order of the day ($\S 5\frac{1}{2} a$, 349 d, 960 a, page 719)? And being so, I will reply, once more, in the language of Dr. Paris, when he was defending medicine against the harmless recreations of the Chemists, about the year 1825, and mainly because Professor Brande had ventured upon the open opinion that chemistry was neglected in medical education, and that the "London Pharmacopæia is a record of the want of chemical knowledge where it is most imperiously required." The answer, perhaps, is abundantly set forth in a former section (§ 676, b). As showing yet farther, however, the instability of science, and as embracing a precept which every lover of truth will do well to ingraft upon his morning prayer, I shall quote Dr. Paris once more, though upon a subject simple in its nature, and of very minor importance to that which is relative to the laws of organic life and the great principles of medical science. Thus:

"I cannot conclude these observations upon Mr. Brande's attack, without expressing a deep feeling of regret, that a gentleman, whose deserved rank in society, and whose talents and acquirements must entitle him to our respect, should have condescended to countenance and encourage that vile and wretched taste of depreciating the value and importance of our most venerable institutions, and of bringing into contempt those acknowledged authorities which must always meet with the approbation of the best, and the sanction and support of the wisest, portion of mankind (§ 676, b). And I shall here protest against the prevailing fashion of examining and deciding upon the pretensions of every medicinal compound to our confidence, by a mere chemical investigation of its composition, and of rejecting, as fallacious, every medical testimony which may appear contradictory to the results of the Laboratory. There is no subject in science to which the maxim of Cicero more strictly applies, than to the present case. Let the Ultra Chemist, therefore, cherish it in his remembrance, and profit by its application:

"'PRÆSTAT NATURÆ VOCE DOCERI, QUAM INGENIO SUO SAPERE.'"-

Paris' Pharmacologia, p. 103. London, 1825, (§ 1034).

And now, for the purpose of showing how any special commentary upon any given substitution for the well-settled method of induction, or for any well-ascertained laws of Nature, is alike applicable to any other fundamental innovation, and how, also, the overthrow of one grand scheme of the day is the immediate parent of another, I shall quote from the Medical and Physiological Commentaries a paragraph relative to M. Louis attempt to foist upon medicine the celebrated

"NUMERICAL METHOD," and ask the reader to apply it to "Organic Chemistry in its Applications to Physiology;" and to "Animal Chem-

istry applied to Pathology and Therapeutics." Thus:

"Thus mounted upon the wreck of philosophy, 'the Numerical Method' ('Organic Chemistry') became the engine in rearing that fabric whose construction it was destined to serve. This is the charm with which the Numerical Method (Organic Chemistry) is invested; while it gives to its author that ascendency in mind which few can truly obtain by the legitimate rules of induction. 'After much deliberation,' as Isocrates says, 'he found the thing could not be compassed in any other manner; or, as our Author has it, 'fortunately for the progress of science, the Numerical Method (Organic Chemistry) is considered by the most judicious and experienced men as a necessary instrument for establishing general principles in medicine' (§ $5\frac{1}{2}$ a, 349 d, 960 a, page 719). Accordingly, former systems, and former facts, fell as by enchantment (§ 3761, 433). The mind sickened at the absence of all principles to guide it, and was therefore the more willing victim when assailed by the irresistible power of numbers (symbols) (§ 960 a, p. 719). If the demonstration was made with reiterated professions of a regard for facts, it was because the method could have had no existence without them; while the perpetual epithet of 'rigorous' left no room for skepticism. But, as related, according to Lord Bacon, 'of good Queen Bess, the Commissioners used her like strawberry-wives, that laid two or three great strawberries at the mouth of their pot, and all the rest were little ones. So they made her two or three good prizes of the first particulars, but fell straightways.' "-(Med. and Phys. Comm., vol. ii., p. 782.)

"This manner of digression, however, some dislike as frivolous and impertinent; yet we are of Beroaldus' opinion,—such digressions do mightily delight and refresh the reader. They are like sauce to a

bad stomach; and we do therefore most willingly use them."

1006, b. The reader will recollect that I had been last speaking of the respect which is due to the experience of the great sages in medical philosophy. I was early led to listen to their conclusions, and to adopt their counsel, as summarily expressed in the foregoing maxim derived from Cicero (§ 1006, a). For thirty years I have watched attentively the effects of bloodletting as practiced by myself and by many others, and have long since come to the conclusion, that it is safer to put "the two-edged sword" into the hands of the ignorant, or the imbecile, or those who make a trade of the profession, than to forever blunt its edges, so that it will not cut, before it be trusted to their use. We every where see victim after victim sacrificed to timid admonitions, and worse example; while you, and all of us know, that it is a rare phenomenon that a patient is slain, seldom in-This is the test, and the strength of it is before jured, by the lancet. the reader.*

1006, c. On the other hand, is it not too often the case that eminent and able teachers, who constantly instruct us to pause where bloodletting is indicated, observe a phlegmatic silence as to the injurious tendencies of active internal agents, or urge them upon us as if they were as powerless as water? These, not bloodletting, make up the great abuses of practice. Here, protestations against abuse would come with a benign effect; or if uttered, they are apt to be in an unworthy spirit of distrust of the whole medical art .-- Note F p. 1114.

^{*} In 1866, after a practice of fifty years, large and without intermission, I reiterate the same. Vide \S 1068, b, p. 870.

Let us at least consider that all other remedial agents of any great importance, even those of the best antiphlogistic nature, are irritants under many circumstances of inflammation, and are, therefore, more or less liable to increase that affection, unless morbid irritability be previously subdued by loss of blood. This is even true of antimonials and ipecacuanha, in irritable states of the alimentary canal. How obvious, then, the importance of often preparing the way for their salutary effects by loss of blood; and, in doing which, we also

greatly supersede the necessity of other remedies.

1006, d. If we contrast even the scanty cases of injury from uterine hemorrhage, and other accidental losses of blood that may be sustained in health (or try our best at the records of excessive bloodletting, as preserved by the most watchful Brunonian), with the terrible and wide-spread effects of procrastination, or timidity, in the use of the remedy where it has been demanded by disease, and, more than all, with the "bark and wine treatment," we shall have little to fear from the possible abuses of the lancet. A few may be rash from ignorance,—perhaps from the encouragement of others; but will not this encouragement stimulate a host to lay aside their fears, and to moderate their Brunonian practice? Where, then, according to the "numeri-

cal method," will be the balance (§ 569, e)?—Notes F H.

1006, e. Where inflammatory diseases are comparatively mild, their mildness will naturally restrain every practitioner; and when existing in severity, there will be little or nothing to fear from the liberal abstraction of blood so long as the symptoms resist this principal remedy, and its proper auxiliaries. At most, there can be only now and then a disastrous result; while timid caution has its myriads of victims. Defective judgment there must always be; and it is better, therefore, that it should lean to the side of safety. If going wrong, the error, in respect to excess of bloodletting, will be very soon discovered. The timidity of man needs no encouragement, when the question relates to "debility," and "the precious fluid" (§ 569, e). But come to cathartics and emetics, nay, tobacco, opium, aconite, belladonna (§ 960, a), he is bold and indiscriminate. Here is opened, I again say, an inexhaustible field of inquiry,-far more abstruse and difficult than the management of bloodletting. You may bleed in intestinal inflammation, perhaps to a vast extent, and speedily surmount the disease; when, had an irritating cathartic been exhibited, the scale might have been as speedily turned in the other direction (§ 878, 893 n, 1063 c, 1064, 1065).

1006, f. Different ages of the world appear to have been distinguished by different degrees of moral firmness, and by remarkable differences in practical habits; and the light of settled experience and of the best philosophy in medicine is almost as apt to suffer a paroxysm of darkness at the advanced as at the earlier stages of science. Certain it is that knowledge had reached a high advance at the time of Hunter, when bloodletting had given a temporary place to the stimulating plan of treatment. Theory and experience governed in one case, hypothesis in the other. No sooner, however, had Mr. Hunter announced the substitution of the stimulant for the depletive treatment, than we hear from Robert Jackson, that "Abstraction of blood in contagious fever, which, but a few years since was viewed with abhorrence, even branded with the epithet of murder, is now considered the main engine of successful treatment" (§ 960, a, p. 717).

And, if we look abroad upon the characteristics of the present day, do we not find in animal magnetism, homœopathy, the humoral pathology, the supplications to the laboratory of the chemist for revelations as to the laws and processes of living beings, in health and disease, and many kindred errors and superstitions, a melancholy com-

mentary on the human mind?

1006, g. The general treatment of inflammatory and febrile diseases having been well ascertained by Hippocrates and his immediate successors, all departures from their philosophy must be of short duration. It will remain forever a model in the science of medicine, as much as Grecian architecture, and Grecian poetry, will continue to be the true models of taste through all coming time. The reason is, that the philosophy of medicine, like the principles of taste, has its foundation in nature, and that, of all her institutions, medicine is the most intensely interesting. The master-spirits of antiquity observed nature correctly, and drew their conclusions from this only source of correct knowledge. They formed no deductions from the distortions of nature, erected no hypotheses upon the ruins of organization, nor sought in the laboratory of the chemist what can be found only in living beings. Drawing their conclusions from Nature herself, they must remain impregnable against all the adversities of time. The fabrics of philosophy may be mutilated; but the breach will be soon repaired, and the offender will find his proper place in the archives of history. Where the foundation has been substantially laid, the innovations of error are like the momentary peltings of the storm upon the "house that is built upon a rock" ($\sqrt[6]{376\frac{1}{2}}, 376\frac{3}{4}$).—Note Ff p. 1135.

1007, a. The general experience of which I have hitherto spoken has been mostly relative to bloodletting in the active conditions of inflammatory and febrile affections. But its advantages are very far from being limited to diseases of a concentrated form, and of rapid progress. They reach, also, and profoundly, the moderated conditions which make up the varieties of chronic inflammation. And here, again, I cannot but entertain the hope that I may have so demonstrated the close similitude of those forms of inflammation which are contradistinguished by the designations of active and passive, that they will cease, at least, to be regarded as extremes of disease that require exactly opposite modes of treatment; and, therefore, that a better practice may obtain in those chronic cases which have been generally consigned to "bark and wine, and an invigorating diet" (§ 752-756. Also, Med. and Phys. Comm., vol. ii., p. 524-546).

1007, b. A few examples will best illustrate and enforce the principle; and to render them emphatic and comprehensive, let us select constitutions broken down by prolonged suffering and wretchedness. An instructive case is recorded by the eminent Kentish. It was the squalid subject of a mortified extremity, which had been advancing to its present state for a year. At this period the leg was removed above the knee. The patient had been crowded for months with tonics and stimulants, and "was reduced to bones." The stump put on an inflammatory action. The admirable surgeon saw nothing but death in prospect, unless he opposed the dictates of philosophy to the prejudices of the lookers-on. "What!" said they, "bleed a poor man who has been confined above a year, and is quite reduced to a skeleton! Oh, shame! shame!" But philosophy triumphed, and ig-

norance stood rebuked. Blood was drawn, and nature began to rally. Still, the system remained oppressed with the effects of former disease, and of former practice. More blood was again and again taken; and at each outlet nature acquired fresh vigor. The inflammation gave way, and the patient recovered. Near a year afterward Kentish saw his patient, who was then, at sixty years of age, a monument of the benefits of science, and of moral courage (§ 863 h 998, 1001). In such cases the hypothesis of anæmia displays its worst

Dr. Borland, a hospital surgeon at St. Domingo in 1796 and 1797, cast away the tonic and stimulant plan which had prevailed, and employed bloodletting and cathartics in the treatment of ulcers. By these means "he often succeeded," says Jackson, "even in persons who were emaciated to the last degrees of emaciation by the contin-

uance of the disease" (\S 992, a, 1057 k).

1007, c. Here is another case of a parallel nature; only more illustrative of the safety and utility of bloodletting in enfeebled states of the constitution, where disease may demand the remedy in more robust subjects. It is a case of diabetes, by Dr. Barlow, in the "Cyclopædia of Practical Medicine." The subject, a boy, was reduced by the disease to a feeble and emaciated state. In this condition he was bled to the extent of 209 ounces, or thirteen pounds, within fifty-one days. The operation was repeated twelve times; so that each bleeding of this emaciated boy averaged seventeen ounces. The result of it was, a rapid restoration of health and strength, and

a return to his plough (§ 992 b, 1032, d).—Note Z p. 1130.

1007, d. Again: "A lady," says Dr. Wardrop, "in a state of pregnancy, had been greatly debilitated," &c. "She was emaciated, and so feeble, that her recovery was, by those around her, considered hopeless. She had a distinct tenderness, on pressure, in the epigastrium, and her pulse, which at first gave the impression of great lauguor, on more minute examination, was very contracted, feeling like a thread, and incompressible, while the heart's action was vigorous. Bloodleting was immediately resorted to, though with hesitation, by the medical attendants. No sooner had a few ounces of blood flowed from the vein, than the pulse began to rise and acquired volume, and upward of twenty ounces were abstracted before its vigor was subdued." Recovery then went on progressively (§ 997).

1008. The foregoing cases of chronic inflammation (§ 1007), which are common in the walks of the profession, concur in showing that medicine is a science of principles, and that a general treatment is universally applicable to inflammation at all stages of its existence, and under all circumstances. Bloodletting may not always be an appropriate remedy; but a low, or non-stimulant diet, may be the prin-

cipal antiphlogistic means (§ 752-756, 960, 975 c, 1006 b).

Of Bloodletting in Infancy and Old Age.

I shall now devote a brief consideration to the applicability of bloodletting to the diseases of infancy and of old age; especially with a view of presenting the experience of a few able practitioners.

1st. Of Bloodletting in Infancy.

1009, a. We have already seen how the operation of remedial agents, as well as the pathology of disease, is more or less modified

by the physiological peculiarities that are incident to the well-marked

stages of life (§ 153-159, 574, &c.).

1009, b. These peculiarities are strongly pronounced in infancy; and, when speaking of that period of life, it was seen that diseases are marked by great activity, and by a rapid progress (§ 576). Hence it is obvious that there should be a corresponding promptitude of treatment, and with remedies that make their impression speedily and profoundly. But, it was also said, that nature is now strongly inclined to the restorative process, and that there is great susceptibility to the action of remedial agents. For these reasons, therefore, the same remedies operate with greater effect than at adult age; so that in many cases where general bloodletting would be indispensable at the latter age, leeching may be equally efficient in infancy; or an emetic, or a cathartic, perhaps, may effect what loss of blood could alone achieve in later life (§ 1008).

1009, c. But, where bloodletting is demanded by the diseases of infancy there is no age at which it is better borne, and none at which its early application is so important. It may be also said, in a general sense, that either general or local bleeding is indispensable in all the grave internal inflammations of infantile life; and that the general method should always be practiced in the cerebral inflammations and cerebral congestions of this age, as of all others (§ 974). In similar affections of other organs, leeching is generally preferable in early infancy, as indicated under the philosophy of the operation of loss of

blood (§ 927 b, 925).

1010, a. The annals of medicine abound with the best experience in favor of bloodletting in the inflammatory affections of infants.

Sydenham remarks, that, "bloodletting may be as safely performed in young children as in adults, and in some of their diseases there is

no curing them without it."

1010, b. Rush was an unhesitating advocate of bloodletting in in flammatory diseases at all stages of infancy. "It is more necessary," he says, "in the diseases of infants, than in adults" (§ 1017, c).

1010, c. Piorry carries bloodletting in the cerebral inflammations and congestions of infants to a great extent,—entirely beyond any thing which I have witnessed; quite as far as quinia in his treatment of indurated spleen (§ 892, k). He employs from one to several venesections, and twenty to fifty leeches to the head, with purgatives, &c. This is, doubtless, excessive; but such is the fatality of infantile phrenitis, and such the ability to bear the loss of blood in cerebral inflammation, that the remedy should have no limit short of affording relief (§ 974, 992 b). Again, it is the experience of this distinguished observer of the effects of loss of blood, that, "in many young children affected with trachitis, large evacuations of blood have enfectled them but little;" though "excessive hemorrhage has sometimes produced convulsions." Such has been my own observation, and also of excessive umbilical hemorrhage. I have seen no resulting death.

1010, d. Evanson and Maunsell think, "that in the child, more particularly, bleeding is required in the first stage of all acute inflammations. It may be practiced with safety in the youngest infant, provided we hold in view the relation between the necessities of the case and the strength of the patient." "The buffing of the blood," say they, "is not a safe guide in the child; as we have diseases absolute-

ly requiring bleeding (e.g., croup, bronchitis, &c.), which seldom pro-

duce the appearance in question."

1011. It is unnecessary to multiply examples of the foregoing experience. They abound in the archives of medicine. Even at an early era of the art bloodletting was practiced as fearlessly in infan-

cy as it was at adult age.

1012. As to my own habits, they have been always uniformly one way. Where inflammation has affected any important organ, or has been otherwise attended with danger, and it seemed not likely to yield at once to milder means, I have taken no risk, but have resorted, without delay, to the remedium principale; nor have I ever had occasion to regret a practice which I would so earnestly commend to others (§ 576, e. Also, P.S. 1860, at p. 872, and Note F p. 1114).

1013. Finally, it cannot be doubted that Lommius is right in the

opinion, that,

"It is much more eligible to snatch a child, by means of bloodletting, from imminent danger of death, however the strength may be wasted, than to let him perish by the violence of the fever."

2d. Of Bloodletting in Old Age.

1014. Here, again, as every where else, we find that physiology lends its powerful aid in the treatment of disease, and agrees with the most enlightened experience. Old age is but a summary expression of all the natural obstacles which have accumulated in the way of the organic functions, and which are about to arrest them forever (§ 580-584, 633). The properties of life are now most incapable of sustaining any of the lesions by which they are invaded at earlier ages. They are approaching their natural extinction, and are readily abolished by disease. They are crippled by physical causes of their own production, and have lost much of their susceptibility to the ordinary effects of remedial agents. Changes from a morbid to a healthy condition are slowly determined,—save only by that remedy which makes its powerful, instantaneous, and simultaneous impression upon the main instruments of vital action throughout the body. In every part the properties of life sustain a deep and abiding effect from loss of blood. Their condition is directly and instantly altered in the instruments of disease, and this alteration is maintained by corresponding reflex nervous influences determined by other parts (§ 514, h), as well as by the continued operation of a diminished volume of blood, and an equalized circulation. The secretions break forth ere we bind up the arm; and thus nature comes to our aid by another efficient process (§ 862, 863). It is all the work of a moment; and the great revolution begun in every part, it may, and often does, terminate speedily in health.

In the formidable diseases of old age, therefore, the remedies must be such as shall reach profoundly the properties and actions of life, and reach them without delay. Such as would be insufficient in youth must surely fail when declining nature is least disposed to co-operate

with art.

1015, a. The foregoing conclusions are amply corroborated by a large and enlightened experience, which equally demonstrates the groundless nature of the prevailing objections to bloodletting in all the diseases of old age; save only those apoplectic affections in which the

system may be least able to sustain the shock of the operation (§

990)

In the Mém. de l'Acad. Roy. de Méd., 1840, is a report by M. Prus, setting forth the safety and advantages of bloodletting as practiced extensively in the inflammatory affections of the aged occupants of the two immense establishments, the Hospice de la Vieillesse, and Bicêtre. He also adds, that, in consequence of the changes which the arteries undergo in aged people, we should always examine the state of the pulse at the heart. "How often," he says, "have patients, whose radial pulse was feeble and irregular, but whose heart announced an energetic action, been bled with the highest advantage, and thus preserved from a speedy and otherwise inevitable death!"

1015, b. Such, too, is the experience of Hourman and Déchambre in their treatment of the inflammatory diseases of the old women of La Salpêtrière; and M. Piorry bears his testimony, that aged men bore the same abundant bleeding (des saignées abondantes) as the old

women of Salpêtrière.

1016. Such, then, is enlightened hospital experience, and only a small proportion of such experience. It is manifest, therefore, that if bloodletting be thus admissible and important with the aged inmates of public infirmaries, there is no ground for that distinction which has been set up, in a general sense, between hospital and private patients, and which enjoins the use of tonics and stimulants in one case where it admits of bloodletting in the other (§ 752–756).

1017, a. But, since "experientia docet," it may be useful to some to be informed circumstantially of what has happened, in the way of

experience, in the private walks of the profession.

Hippocrates, Galen, Celsus, Trallian, and other ancients, advocated bloodletting in the inflammatory diseases of old age. "In bleeding," says Celsus, "the physician should not consider so much the age as the strength of the patient."

1017, b. We are told by Wepfer that it is a very prevailing custom among the Swiss, even at eighty and ninety years of age, to resort to

bloodletting once a year, or oftener, as a prophylactic.

"I admonish you," says Vitel, "against the advice of those physicians who would dissuade you from bleeding the aged, who may be the subjects of inflammatory or eruptive fevers. The fear of debility is unfounded. Bloodletting is as necessary to them as to the young,

and not less beneficial."

F. Hoffmann remarks, "Communis, sed pessimus error est, ætatem senilem plane non ferre sanguinis subtractiones, quasi vero in grandævis non redundaret sanguineus latex, ut potius ejus et virium de fectu laborarent." "In senili ætate magis necessaria sanguinis missio, quam alia ad morbos grandævis familiares arcendos," etc. "Venæsectio sepius senibus utilissima, imo ad longævam vitam confert." "Complura certe memoria teneo exempla senum, qui ad nonagesimum annum fere, salvi, incolumes et a morbis ætate provectis familiaribus immunes vixerunt, solo venæsectionis remedio, bis per annum admisso." "Id quod etiam a me in peculiari dissertatione, De Magno Venæ sectionis ad vitam sanam et longam Remedio, assertum est ac demonstrandum."—Opera, t. i., p. 135, 455, 456.

Forestus bled the aged equally without hesitation,-" firmus puer.

et robustus senex, tuto curantur."

Van Swieten, the able practitioner and learned commentator, considers bloodletting as important at the extremes of age, as at the in-

termediate periods.

Finally, all the best writers of the sixteenth and seventeenth centuries advocate bloodletting for the inflammatory and febrile diseases, not only of middle age, but at the extremes of life. They protest, also, against arresting spontaneous hemorrhages, even when occurring at advanced age. The Brunonians have looked on with admiration, when nature has thus rescued the sick from the evils of the bark and wine treatment (§ 890, e).—Notes Ff p. 1135, Gg p. 1138, II p. 1139.

1017, c. In later times, the records of medicine continue to abound with demonstrations of the safety and necessity of bloodletting in the

inflammations and fevers that may befall old age.

From what was stated of Rush's experience of bloodletting in infancy (§ 1010, b), it appears that he considered the remedy most important at the extremes of life; for, in another work, he says, "Experience proves that bloodletting is more necessary, under equal circumstances, in old age, than in any other."—(See my Examination of Reviews, in Med. and Phys. Comm., vol. iii., p. 76-78.)

Hosack deprecates the prejudice which exists against bloodletting

in old age.

Sir G. Blane demonstrates the safety and utility of the remedy in the inflammatory diseases of aged people. He states the case of an individual at the age of one hundred years, who was cured of pneumonia by free bloodletting from the arm. In another instance, a lady of eighty-two years suddenly lost, by spontaneous hemorrhage from the nose, a quart of blood, "which was followed neither by faintness nor weakness, but by improvement in health, in point of vigor and alacrity."

Frank cured an octogenarian of pneumonia by bleeding him nine times. Gui Patin cured his father of pneumonia, at the age of eighty, by bleeding him freely from the arm eight times. Freteau bled at the

age of seventy to the extent of four pounds in six days.

And thus might I go on with numerous other coincident authorities; all showing individually, and proving collectively, that old age, per se, constitutes no objection to loss of blood. But, were there even hazard in the remedy, its possible dangers would be incomparably less than those of many acute diseases which now so readily destroy. It is no defense that the patient dies naturally, when the chances of life are withheld by the neglect of bloodletting.

Spontaneous Hemorrhage.

1018. I shall now briefly consider nature in her efforts to relieve the system of inflammations and congestions; since it is from the various expedients of Nature that we derive many of our best indications of cure; and the summary mode in which she institutes the hemorrhagic process, and the consequent relief of protracted diseases, are alone conclusive against the Brunonian doctrine of debility, and may encourage the timid practitioner in the use of the lancet (§ 862, 863, 890 e, 990 m).

1019, a. John Hunter has seen several quarts of blood thrown up from the stomach in a few hours, even by emaciated patients; and recovery has speedily followed the evacuation. Cases of this nature

are witnessed by all practitioners of much experience. The same immense quantities of blood are often discharged from the lungs, and intestine; breaking up the most formidable congestive fevers, and chron ic inflammations which have resisted all other means of treatment for years (§ 733 d, 890 e).

1019, b. Lancisi relates the case of a man of seventy years of age, who suddenly lost, in a threatened attack of apoplexy, eleven pounds of blood from his nose, and four more in fifteen days afterward, with-

out any sensible failure of strength.

1019, c. Boerhaave "has known almost the entire blood of the body to have been lost by hemorrhage, and yet the subject recover."

1019, d. Haller relates many examples of excessive hemorrhage. In one of his cases, one hundred and twenty-five ounces of blood were lost at each menstruation, for several years; besides a daily abstraction of blood from the arm for fourteen months. In another instance, he states that one thousand pounds, or four barrels of blood, were lost in one year, or nearly three pounds daily for that period. In another there was a hemorrhoidal flux of five pounds daily for sixty-two consecutive days, or a total of three hundred and ten pounds; being probably twice the weight of the whole body. One more lost one hundred and ninety-two ounces, or about thirteen pounds, from his stomach, in a single night, and recovered. Haller, himself, lost one hundred and twenty-eight ounces, or eight pounds of blood, within twenty-four hours.—(See special references in Med. & Phys. Comm. vol. i.)

1019, e. Similar examples are constantly presented to our observation, and a large variety may be found assembled in the Medical and Physiological Commentaries. They show us that when Nature takes the work in hand she does not stop to calculate the ounces, or the pounds, but pushes on till she has accomplished a rational purpose. "Honest Brunonians," says Dr. Beddoes, "have, of late, minutely recorded cases, to them incomprehensible, where immense discharges of blood have suddenly stopped protracted fever, and left the patients improved in strength" (§ 890, e, 993).—Notes Ff p. 1135, Gg, II.

1019, f. Among the multitude of these extraordinary hemorrhagic effusions it is rare that death is an immediate consequence (§ 890, e), and rarer still where art has superintended the loss of blood. In the latter case, syncope comes, in good time, to the aid of the patient; far sooner than in the spontaneous process. Nor can art imitate nature in the full extent of her depletory system. The philosophy which respects the difference in effects appears to be this. remedy is instituted by nature, the parts concerned in the morbid action are made the instruments of relief, and the general law of adap tation is in force (§ 137 c, 733 d, 847 g). The peculiar modification of action upon which capillary hemorrhage depends, and the influence it exerts upon the system at large, resist the earlier effects of loss of blood when artificially abstracted in the same way as the loss is resisted by inflammations. I have seen this principle operating with various effect in inflammations, according as they are modified by remote causes, and according to the activity and extent of disease, the organ or organs affected, &c. (§ 805, 813, 922 b).

1019, g. The more we interrogate nature as to the loss of blood the more shall we find her proclaiming that this is her expedient, beyond any other, by which she attempts the removal of fearful diseases.

Hæmoptysis, hæmatamesis, the hemorrhoidal flux, intestinal hemorrhage, are all instituted for this purpose. We constantly witness the spontaneous effort where the properties of life are so prostrate that art looks on with dread and amazement; and what nature had thus wisely begun is often declared to be the effect of a putrid disruption of the living body, and calls for every counteracting means. Fortunately, these means sometimes consist of the lancet, and other antiphlogistic remedies. But this, with many, is only where the strength is vigorous, and where it is feared that unrestrained nature may possibly reduce it. Examples of this kind are common in pulmonary hemorrhage; and, although in these instances the blood be taken with a view of astringing a suspected rupture of a blood-vessel, the error does not affect the true philosophy of the case; and when nature may be too "sparing of the vital fluid" to overcome the real condition of the lungs, a singular illustration will be obtained of a co-operation of the lancet toward a salutary result where it had been employed to defeat the curative effort of nature (§ 922 b).

1019, h. But error is often committed in these cases. If hemor rhage be profuse, it should be allowed to go on within the limit of safety; since the depletion proceeds from the instruments of disease. A rapid abstraction of blood from the arm, superadded to the hemorrhage, may arrest the spontaneous discharge too speedily; while that which is artificially taken would be more curative if left to the natural process. But, again, where the spontaneous discharge is small, the lancet may be imperatively demanded; while it is here employed with greater caution than in the former cases.—Note F p. 1114.

Of misapplied and excessive Bloodletting, "Morbid Irritation," and "excessive Reaction from Loss of Blood."

1020. In the Medical and Physiological Commentaries I have investigated extensively those reputed consequences of loss of blood which are known as "morbid irritation, and excessive reaction" (vol.

i., p. 239–281).

1021. We certainly meet with examples of the foregoing nature, arising from improper bloodletting. But, it is generally too little, not too great a loss of blood, which does the mischief. The untoward results are owing to the unfavorable impression which is thus made upon the organic properties, both by the direct effect of the agent, and by the operation of the nervous influence upon the heart and the main instruments of vital action (\S 965, b). The heart, in consequence, beats either with greater frequency or greater force. This is what is denominated "irritation" and "excessive reaction," and is assumed as a proof that too much blood has been abstracted; when, on the contrary, had the loss been carried to a greater extent these phenomena would have been rarely presented (\S 500 m, $687\frac{1}{2}$, $694\frac{3}{4}$).

1022. And now to show conclusively that the foregoing consequences depend more or less upon imperfect bloodletting, and a consequent aggravation of disease, it will be found, as I have shown extensively in my former Essay on Bloodletting, that in most of the cases recorded by Dr. Marshall Hall and other advocates of the doctrine of "excessive reaction," that the symptoms and post-mortem appearances, as by themselves recorded, denote either the antecedent existence of inflammation and a subsequently exasperated degree, or inflammation

resulting from the loss of blood, or from an antecedent predisposition. The last two causes may act conjointly; and, as I have already shown, too small an abstraction of blood is not an unusual cause of inflammation. Excessive bloodletting, on the other hand, is a rare phenomenon; but, unlike too small a loss, it may establish inflammation in-

dependently of any antecedent predisposition (§ 950, 965 b).

1023, a. When inflammation is induced by excessive loss of blood, the physiological influences are not the same as those which obtain when it ensues upon, or is aggravated by, too small a loss (§ 965 b, 1022). In very numerous cases of this nature there has been a preexisting tendency to the disease; or, more frequently, a morbid condition already established, but not fully developed. Thus, it is not an unusual event that the physician abstracts blood for pain in the head, or a "stitch in the side," or for some uneasiness of breathing. The abstraction of blood is judiciously moderate. But, there has been an accumulating tendency to inflammation; and the blood thus abstracted proves not to have been commensurate with the demands of the case. It releases and gives force to the general circulation, and increases the irritability of the extreme vessels. Phrenitis, pneumonia, or pleuritis, is the consequence. The physician is alarmed by the unexpected event; yet so like inflammation are the consecutive symptoms, that he ventures upon the lancet for their relief. But, the symptoms had followed upon the loss of blood, and his decision is restrained. He therefore stops at the very point of mischief, and adds another impulse to disease. He may yet bleed again and again, as the malady resists all other agents; but the same caution prevails, and the evil increases at every partial outlet of blood (Note p. 729).

These cases accumulate rapidly upon the hands of the unskillful or timid. Records are examined, and parallel examples are found to abound. Dissections are made, and reveal the usual physical signs of inflammation. The conclusion, therefore, comes up, as expressed by Dr. Hall, that there is a disease "exactly like inflammation, but

totally different from it"!

Just so it is with child-bed women. There is often a great tendency, in these cases, to local inflammations; and these may be more or less speedily developed by moderate flooding, especially if there have been previous venous congestion, as is very frequently the case (§ 803, 965 b). Dr. Hall has many of these examples, and were they really cases of simple irritation, or simple exhaustion and excessive reaction from loss of blood, they could not be adduced to illustrate the effects of bloodletting in disease. They should form a class by themselves; designated as cases of the morbific effects of "excessive loss of blood" upon the comparatively healthy system. They must, therefore, be admitted to have no bearing upon cases where bloodletting may have been demanded, and to be worse than useless for illustrating the effects of bloodletting as a remedy. As well might one say, that cathartics shall not be given in disease, or only so with fear and trembling, because they may be pernicious in health. And he, being well, who should physic himself in order to be better, would be mad indeed should he attempt to remove the evils of his mistake by swallowing one dose after another. Just so it is in respect to bloodletting, or accidental hemorrhage, in health. If inflammation follow in the latter instance, it will be important to ascertain whether excessive

bloodletting have been the exciting cause, or whether it did not spring from a previous disposition to disease; since the treatment will be entirely different in the two cases. The former case is rare, as known from the accidental and profuse hemorrhages that are daily occurring. Nor is even simple irritation a common result; the injury consisting mainly in feebleness. And here I may say, that it is a remarkable fact, that the effects described by Dr. Hall as incident to lying-in women rarely supervene upon excessive flooding; thus showing that in the cases of disease the affection existed already, or was

about taking place.

1023, b. When, however, inflammation is actually induced by excessive loss of blood, the effects of the physiological influences are different from those which I have set forth as constituting the philosophy of the operation of loss of blood, as the effects are morbific in one case, but are not so, or are curative, in others. The modus operandi, however, is exactly the same in all the cases; and, being so, the morbific effect confirms my philosophy of the modus operandi of the curative influences. In the former case, an injury is inflicted, suddenly, and severely, upon the vires vitæ of all parts, and the nervous influence is powerfully determined upon all. The brain suffers the impression particularly; and if "irritation," or "excessive reaction," follow, I know of no recorded instance which has not also presented the usual phenomena of inflammation, either in the brain or some other organ. If death ensue, effusions of serum, or of lymph, or disorganization, &c., are the concurring results. Still, however, another cause, and not the loss of blood, may have produced the disease, and have been overlooked, as is most probable (§ 1006).

1024, a. Dr. Hall, who, particularly, called our attention to the foregoing "irritation," and "excessive reaction," as frequent effects of excessive loss of blood, and distinguishes those conditions from inflammation, concedes that "exhaustion from loss of blood is not only not incompatible with repletion and a tendency to effusion within the head, but it actually supposes that condition of the encephalon, when long protracted." He also states that leeches to the head are one of the remedies. So, too, may general bloodletting relieve the symptoms, but only temporarily in the cases supposed; since, when inflammation is induced by an excessive loss of blood, such is the combined nature of the exciting cause and its curative effects the modified irritability of the vessels may readily yield, at the moment, to a farther loss, but will soon display the morbific influence (§ 901).

1024, b. In my remarks upon the physiological effects of bloodletting I endeavored to show that, when the loss of blood is carried to a state of syncope, and more especially to any injurious excess, the greatest severity of its influence is sustained by the brain (§ 950). It is to the head, then, that we should generally look for the local injury, if any attend the reputed cases of irritation and exhaustion from an excessive loss of blood. This is precisely what we find stated by the late writers who have treated of this subject; at least in a general

sense.

1024, c. But, as the question under consideration is of no little practical importance, it may be well to have before us Dr. Hall's highly-descriptive account of the severe grades of what he calls "exhaustion with excessive reaction," and as supplying the most ample proof that

the supposed condition is, in reality, a state of active inflammation. Thus:

"The beating of the temples," says Dr. Hall, "is at length accompanied by a throbbing pain of the head, and the energies and sensibilities of the brain are morbidly augmented; sometimes there is intolerance of light, but still more frequently intolerance of noise and of disturbance of any kind, requiring stillness to be strictly enjoined, the knockers to be tied, and straw to be strewed along the pavement; the sleep is agitated by fearful dreams, and the patient is liable to awake or to be awoke in a state of great hurry of mind, sometimes almost approaching to delirium; occasionally even continued delirium; more frequently there are great noises in the head, as of singing, of crackers, of a storm, or a cataract; in some instances there are flashes of light; sometimes there is a sense of great pressure or tightness in one part or round the head, as if the skull were pressed

by an iron nail, or bound by an iron hoop."

1024, d. Now, the foregoing symptoms, which Dr. Hall considers as denoting a state exactly opposite to that of inflammation when they attend considerable losses of blood, are precisely such as are characteristic of cerebral inflammation when induced by other causes. But, as if to remove all doubt as to this conclusion, this distinguished philosopher reiterates the foregoing account, and designates other phenomena not less significant of cerebral inflammation, such as "frequent delirium," "hardness of pulse," "buffy blood," &c.; and, to give to the subject its utmost force he calls to his aid the opinions of Cook, Coke, Kellie, Tweedie, Hammond, Cox, and others; all of whom agree in testifying to the symptoms that mark, exactly, the character of inflammation of the brain. Nay, more, he allows this conclusion,—that they are "attacks which resemble inflammation of the head, chest, or abdomen, and yet are totally different in their nature."

Thus then, as to our author's excellent description of the general phenomena, which he imputes to this disease that is considered so opposite to inflammation, they are, to my mind, conclusive against our

author's doctrine.

1024, c. Morbid anatomy contributes, also, its corresponding proof. "The next point for our consideration, in the inquiry into the morbid effects of loss of blood," says Dr. Hall, "will be that of the organic changes induced during the state of sinking. These are chiefly observed in the brain, in the cavities of the serous membranes, in the bronchia, in the lungs, and in the track of the alimentary canal, under the forms of effusion, ædema, and tympanitis." At other times, our author admits of morbid redness, and absolute disorganization, as rapid consequences of this affection so opposite to inflammation.

1024, f. Such, indeed, is the entire coincidence between our author's supposed cases and those of inflammation, that we are told by the author that there is often no other test of their distinction than the treatment which is adapted to inflammation. We must bleed; and if the patient bear it well,—well;—if otherwise, we must then endeavor to repair the wrong. This after-knowledge, this dependence for the diagnosis upon the effects of treatment, may help the understanding; but will it be likely to help the patient, or to improve the science? And how is the treatment improved by this species of intelligence? The greatest zealot would abandon the diagnostic test

if he found it injurious. But, says Dr. Hall, the patient "may be greatly relieved by the loss of blood;" "the temporary relief which follows general bloodletting may be so uniform as to impose on the

inexperienced." Then I maintain that the loss is useful.

1024, g. In the foregoing cases, as related by Dr. Hall, and others, where there had been bloodletting, we may generally recognize the occurrence of cerebral inflammation independently of the loss of blood, and often of its pre-existence; and I as sincerely believe that farther bloodletting was the proper remedy for the disease. In the cases where irritation, and excessive reaction, are said to have been consequent on spontaneous hemorrhage, it is not less apparent that, in most instances, inflammation had already existed, or there was a strong predisposition to it.

1025. There are few practitioners in the United States who have seen more of bloodletting than myself; and I am therefore quite conversant with cases of the foregoing nature, as I have met with them in the hands of others. In numerous instances where the attending physician had imagined "excessive reaction, and prostration from excessive loss of blood," I could discover nothing but the onward march of inflammation, that called for greater abstractions of blood; and that this opinion was right has been generally confirmed on resuming the

depletive treatment.—Note p. 763.

1026. Finally, as I have said in the "Commentaries," the rules for bloodletting which have been propounded by Dr. Hall, and all others of a like nature, are captivating by their simplicity. This was the secret of the popularity of Brown's Elements of Medicine, and of the long, unmolested sway of the Humoral Pathology. A later and more universal example is seen in the chemical views of life and disease.

Many have imbibed an erroneous impression that Dr. Hall is a warm advocate for the use of the lancet; and, as the case of Dr. Hall is very extensively applicable to physicians, I shall state the nature of the misapprehension. Dr. Hall advocates bloodletting only in certain affections where few would deny the propriety of the remedy; and in such cases he commends its liberal use. But, what he has so far said with emphasis has the effect of discouraging its application in the vast class of congestive fevers, and depressing inflammations, and even in many of the cases to which, on general principles, he admits its applicability (Rights of Authors, p. 913, and Index II, art. Hall, M.).

But it is not alone by his exclusive precepts that his purpose is attempted. On more than one occasion he broadly affirms, that "it is difficult to say whether more injury has been done by an undue, or by an inefficient, use of the lancet." Such is the balance which is often struck by apparent advocates of bloodletting; but, I am still apt to think, with Botalli, that "One hundred thousand men perish from the want of bloodletting, or from its not being timely employed, where one perishes from excessive bleeding, when prescribed by a physician."

General Conclusions as to Bloodletting.

1027. From all that has been now said on the subject of bloodlet-

ting, I arrive at the following general conclusions:

1. That loss of blood produces its direct and efficient impression upon the *vires vitæ* of the capillary blood-vessels, by modifying their action.

2. That the quantity of blood to be abstracted relates directly to

the foregoing impression.

3. That the most salutary effect of loss of blood will, therefore, consist in its nearest approximation to a full but just impression upon the vires vitæ.

4. That, to produce and maintain the foregoing impression will require the abstraction of a certain quantity of blood in every case, the measure of which will be the antecedent and resulting symptoms.

5. That bloodletting may add to the force of disease by coming short of that impression; or, it will be injurious if carried to excess, or may even induce new inflammations.

6. That bloodletting may be a remedy for other diseases than inflammation and fever.

7. That, when employed as a prophylactic, on passing from northern to tropical countries, it must be with such moderation as shall not increase irritability; and then only in the plethoric and robust.

8. That general bloodletting, cupping, and leeching, operate upon common principles, which are more or less modified in each mode of abstracting blood. That cupping is intermediate, in this respect, be-

tween general bloodletting and leeching.

9. That general bloodletting is a far more important remedy than leeching; and that, while cases constantly arise in which the latter cannot be substituted for the former, there are numerous instances in which general bloodletting cannot take the place of leeching. cupping will sometimes answer the purposes of either, and may be,

though rarely, better.

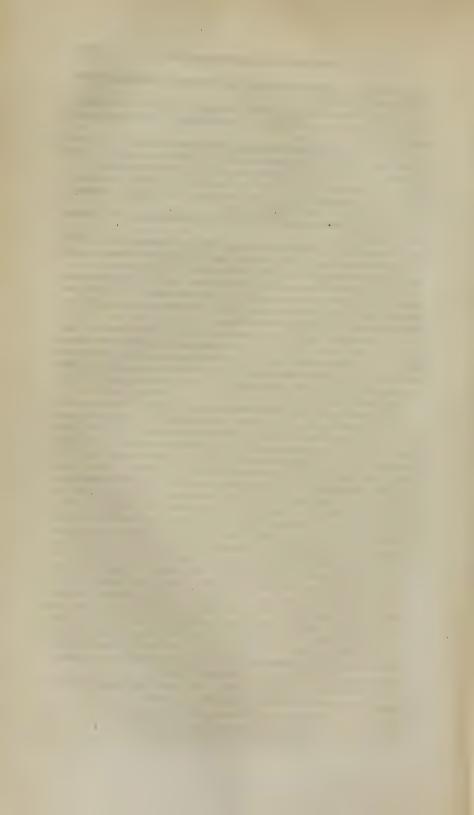

10. That the nervous system has a special and large allotment in the effects of loss of blood, and that loss of blood operates, in the first place, by inducing a profound effect upon the extreme blood-vessels when the influence thus exerted is propagated by sensitive fibres of the sympathetic or nerve of organic life upon the nervous centres, the nervous power excited, and then reflected through excito-motory fibres of that nerve upon the sanguiferous organs, and with a special alterative effect upon the susceptible capillary blood-vessels that may carry on the morbid process, that, when the vessels of the nervous centres contract, the reflex nervous influence is increased by the projection of a direct development of that influence upon the sanguiferous organs, and that these influences multiply in an increasing ratio till syncope takes place.

11. That in bloodletting five principal objects are contemplated: 1. To reduce the volume of blood. 2. To thus establish a change of action in the capillary blood-vessels. 3. To thus obtain the alterative action of the nervous influence. 4. To reduce the exciting nervous influence attendant on inflammation and fever, whether reflex or direct, that disease shall abate, and that cathartics, counter-irritants, &c., when necessary, may operate without exciting a morbific reflex nervous action. 5. To thus, also, prepare the way for other remedies by promoting their salutary effects and preventing their deleterious, which have equally a

reference to the condition of the nervous influence.

12. That spontaneous hemorrhage, occurring at adult age, should not be restrained, unless manifestly proceeding to excess.

"Truth, like a single point, escapes the sight, And claims attention to perceive it right; But what resembles truth is soon descried, Spreads like a surface, and expanded wide."-Pomfret.

APPENDIX.

PROGRESS OF "PHYSIOLOGICAL AND PATHOLOGICAL CHEMISTRY," OR "EXPERIMENTAL MEDICINE,"

1028. During the former editions of the foregoing work the Author has seen no inducement to modify any of his conclusions, or to disturb any of the facts upon which they are founded, and, for the same reason, every statement appears in the present edition (1857) as presented originally in 1847. Whatever may have been subsequently disclosed in Physiology and Chemistry is essentially in harmony with all that the author incorporated in the foundation upon which his Institutes are erected, and places them beyond the probability of being much invalidated. In his discussion of Organic Chemistry as applied to Physiology, Pathology, and Therapeutics, it is evident that he could not doubt that this invasion upon Medicine would prove ephemeral, and that the Chemist would soon retreat into the appropriate field of Nature. (§ $4\frac{1}{2}d$, $5\frac{1}{2}$ –6, 18, 42–67, 349a, $350\frac{3}{4}n$, 351, 356, $376\frac{1}{2}$, 435c, 676b, 960d, 1006a, &c.)

These expectations have been realized sooner than the author had anticipated, as he will now show, for the benefit of his junior readers, by a few extracts from one of the latest and most approved works upon Organic Chemistry, by the justly celebrated Professor Lehmann. It is true, our Author has favoured us with an able and elaborate Treatise in behalf of "Physiological Chemistry;" but whoever may peruse its pages will everywhere discern the obstacles which necessarily beset his path, and the vagueness of his conclusions, and many unavoidable contradictions, after having discarded those indispensable elements which are summarily involved in the following quotations, and which amount to a virtual admission that we must seek in the doctrines of vital solidism for the only true philosophy of life and disease. Thus, our Author:

1029. "As soon as we subject to investigation the highly complicated chemical phenomena of life, we enter upon the actual domain of hypothesis. It unfortunately happens, however, that the correct logical conception of an hypothesis has been completely lost sight of, and its place supplied by the vaguest fictions; whence the term has fallen into such discredit that many have been desirous of setting aside all hypotheses, unmindful that even the simplest form of experiment cannot be pre-

sented without their aid.

"Physiological Chemistry has given rise to many delusions of this nature, owing to its imperfect development, and to the necessity presented by Physiology and Pathology for chemical elucidation. Some few isolated deductions were drawn from superficial chemical experiments, and arranged in a purely imaginary connection by the aid of chemical symbols and formulæ, for whose establishment analysis in many cases did not afford any sanction. Thus, for instance [a very important and comprehensive example], in the attempt to form a conclusion regarding the meta-

morphosis of the blood from an elementary analysis of its solid residue, and of the composition of the individual constituents of the excretions, there is an utter absence of all scientific groundwork; for, independently of the fact that the elementary analysis of so compound a matter as the blood is incapable of yielding any reliable results, and cannot, therefore, justify the adoption of any special chemical formula, it is surely most illogical to attempt to compare the composition of the blood collectively with that of the separate excrementitious matter. In such deductions, expressed by chemical formulæ, the addition of atoms of oxygen, and the subtraction of those of water, carbonic acid, and ammonia, are wholly arbitrary, for chemical analyses do not afford the slightest grounds for the majority of these equations."* "Chemical equations having no other foundation than the presumed infallibility of empyrical formulæ, must cause us to deviate from the path of physical inquiry, and involve us in a chaos of the most untenable delusions." (Vide Liebic § 50, 409 b).

"Have the numerous analyses of morbid blood instituted during the last few years fulfilled the expectations of Physicians? (§ $5\frac{1}{2}$, a.) With all due gratitude to the indefatigable investigators who, with no other aid than that which zoo-chemistry could offer, boldly attempted to throw light on those obscure inquiries, it must be admitted that, when we seriously inquire into the recompense of all their labors and sacrifices, we find that the result, although too dearly bought, was altogether inadequate to satisfy the requirements of Pathology. (§ 3761.) Have the numerous analyses of the urine led to much more than the assumption of several new species of disease, or so-called diatheses? (§ 427, 691.) Although we might have anticipated greater results, we can hardly wonder that the efforts hitherto made should either wholly or partially have deceived our expectations; for although these investigations may have rendered chemistry no unworthy auxiliary to a physical diagnosis, analyses of morbid products can hardly afford an insight into the chemical laboratory of the organism, while the means are wanting to prosecute them with the scientific accuracy attainable in the case of mineral analyses. Animal Chemistry is still wholly unable to afford us a precise, and at the same time a practically useful method of investigating the blood; and how should it be otherwise while we continue to be in doubt regarding the chemical nature of its ordinary constituents? The mineral substances of normal blood are not yet determined, or, at all events, continue to be made the subject of dispute; we scarcely know the names of the fatty matters it contains; one of its most important constituents, fibrin, cannot be chemically exhibited in a pure state; we are ignorant of the nature and mode of secretion of the globulin of the blood-corpuscles; we are still far from being able to separate and determine the so-called protein oxides (§ 18, 53 c, 409 a, b); and we are also ignorant of the excrementations substances occurring in the blood. How, then, amidst these and a THOUSAND OTHER UNCERTAINTIES AND DOUBTS, can an investigation of the blood be scientifically and trustworthily conducted? We analyze healthy and morbid milk, and yet we are ignorant of the substances whose admixture we have termed casein. The urine, in its morbid conditions, presents many varieties; and yet our knowledge of that secretion, frequently as it has been analyzed, amounts to little more than an acquaintance with the quantitive relations of some of its principal constituents; creatinine and hinnuric acid have not been determined by any analysis, while absolutely nothing is known regarding the most important pigment of this secretion. * This sustains my criticism of Liebig, p. 221-222, 6 409 b.

Many experiments have been made and theories broached on nutrition and digestion, and yet to almost the present day the existence of lactic acid in the gastric juice has been contested. Although hypotheses are not wanting regarding the mode of action of Pepsin, we know nothing of its nature (§ 363-365), and we are wholly ignorant of the proximate metamorphosis of albuminous bodies in the stomach during digestion. Will Mülder be able, even with his most accurate analyses, to support his protein theory by the aid of sulphamide and phosphamide? Or is this term destined to indicate a past epoch of Organic Chemistry? (§ 38–51, $350\frac{3}{4}$ n, $376\frac{1}{2}$, 409 a, b.) When such is the state of Organic Chemistry, can we wonder that there should be obscurity regarding the chemical processes in the animal body, their various isolated and combined actions, their casual connection, and their dependence on external influences and internal conditions? Unfortunately, we might be led to believe, from the lectures and writings of many physicians, that, trusting to the aphoristic and often highly apodictic assertions of certain chemists, they felt secure of having reached the object of their inquiries. (§ $5\frac{1}{2}$, a.) Although at present LITTLE MORE THAN THE DIRECTION is indicated, we may hope in due time, and after innumerable efforts, to see our endeavours crowned with success!" And so said Fourcroy seventy years ago, p. 9, \$5, 376½. From all which, it appears that our friends are upon the wrong track.— Professor Lehmann's Physiological Chemistry, vol. i., p. 19, 23, Philadelphia, 1855.

1030. Again, we have a summary admission from this eminent Chemist which shows us forcibly that there can be no dependence upon organic analyses for any knowledge of the natural or morbid processes or products of the living body—not even, indeed, of the elementary constitution

of the tissues in their natural condition. Thus:

"The theory of the chemical nature of the animal tissues is a department of physiological chemistry which, as yet, has been very little cultivated, and the reasons of this unsatisfactory state of our knowledge are too obvious to require any detailed exposition. We will, therefore, simply observe, that the most important obstacle to the chemical investigation of the tissues is, that their elements are too intimately combined or associated with one another to admit of their being prepared for chemical analysis by a previous mechanical separation. This separation of the various elementary tissues which are deposited among, penetrate between, and envelop each other, is rendered the more difficult by the circumstance that, with scarcely an exception, they are equally insoluble in the ordinary indifferent menstrua employed by chemists. If we have recourse to the stronger or more energetic solvents, as, for instance, acids and alkalies, we have seldom any assurance that the dissolved substance is the, otherwise, unchanged histological element, and the portion remaining undissolved is, in reality, a simple chemically pure material. Indeed, in a majority of cases, there cannot be a doubt that the chemical constitution of the tissue on which we are experimenting is entirely changed by such reagents" (§ 53 b, 417 a). And so of the blood and secretions, § 1029. (Professor Lehmann's Physiological Chemistry, vol. ii., p. 174.)

Among the many very luminous comments by which our author discredits organic analyses we should naturally expect to find the same discouragement of pathological chemistry. On entering upon the consideration of "Exudations and Pathological Formations," he remarks

that,

"We have often had occasion to comment upon the inefficiency and imperfection of our chemical knowledge, when compared with the great expectations which have been entertained in respect to its applications to Physiology and Pathology; yet there is scarcely any subject which more thoroughly calls for our confession of weakness and incapacity than the one we are now about to consider" (§ 5, $376\frac{1}{2}$, $676 \, b$, $1006 \, a$). Again: "The science of Pathological Histology, which alone can guide the Chemist, is so full of uncertainties, subjective conceptions, and varying conjectures, notwithstanding some signal advances, that it scarcely ever presents any starting-point for chemical investigation."—"A Chemist cannot be satisfied that he knows a substance until he has submitted it to an elementary analysis, and can attain, at all events, an approximate determination of its atomic weight. In fact, a body which has been submitted by the Chemist to a few reactions only, however striking they may be, but for which he is unable to establish a formula based upon elementary analysis, may be almost considered as unknown to him (§ 1029). In this sense (and in exact investigations we can only take this view) all substances, as transition stages from the protein-bodies of a plastic exudation, are wholly unknown to us, and must remain equally unexplained until we are able to elucidate the mystery of protein" (§ 18 d, e, 53 b, 409 a, b). The troubles multiply after death, among which is the "rapid decomposition, even while the body is yet warm," and upon which we have quoted a luminous remark of Tiedemann in § 54, a. "In a word," says our Author, "while even the quantitative investigation of objects derived from healthy animals has to contend with such difficulties that very few animal juices admit of being very accurately examined, the qualitative analysis of pathological products is opposed by insuperable obstacles." "If, therefore, we have very slight prospect of being able to trace pathological processes by a qualitative examination of exudations, or of attaining any scientific aim by such a mode of procedure, we are led to inquire, with some hesitation, whether the quantitative analysis of these products would be attended by any better results."—Lehmann, ibid., vol. ii., p. 271-274.

I have taken the liberty of placing many of our Author's words in italics and capitals, and have introduced references to Sections in these Institutes, and shall preserve this plan hereafter for the sake of the reader's eve, and, more or less, as a substitute for comment. Many of the remarks which I have rendered emphatic in all the foregoing quotations express a fundamental fact, which vitiates all organic analyses beyond the mere disclosure of a probable elementary composition. Upon this I have hitherto insisted as an insuperable difficulty (§ 53, b, &c.). I may also say, in explanation of my general silence upon our Author's facts and hypotheses, that I am not aware of any one whose essential nature I have not examined and controverted in the foregoing work. But a better reason may be found in the consideration that our Author has. himself, surrounded his facts and hypotheses, throughout his work, with admitted doubts, distrust, and ambiguities, of which the foregoing are but a few examples. It is, however, an able, but, as appears to me, an abortive attempt to reconstruct the fallen fabric of Organic Chemistry. Our Author is merciless upon the past, and, as our extracts show, is almost hopeless for the future (§ 626 b, 819 b, and Notes, pp. 196, 911).

PRODUCTION OF ANIMAL SUGAR.

1031, a. It is now my purpose to bring under the test of the foregoing results of chemical experience, as well of certain physiological principles, the new function which has been lately ascribed to the liver of generating sugar, in connection with the supposed mechanical filtration of sugar from the blood by the kidneys and mammæ. But, independently of this great incongruity between the supposed catalytic action of the liver and the mechanical office of other complex glandular organs, we are startled with the announcement that the liver is a farther exception to the principle of analogy in discharging multiplied and perfectly distinct functions in the economy of life. "Qu'il résulte de là que le foie n'est pas un organe simple, mais un organe à fonctions multiples, puisqu'il sécrète d'une part du sucre, de l'autre de la bile."—Cl. Ber-

NARD, Leçons de Physiologie Exp., &c., p. 88; 1854, 1855.

Without, certainly, denying the alleged fact in respect to the liver, it is proper to inquire into its probability until it becomes established, and in doing this we shall have analyzed some important facts in their relation to the functions of glandular organs. Should the supposed formation of sugar by the liver, as a product distinct from the bile, and destined to subserve totally different purposes, be rendered no longer doubtful, we shall hail it as a remarkable accession to physiological science, however much it may disturb any supposed principles, or however little may be its practical bearings; and, whatever may be the final issue, nothing can detract from the great merit of the inquiries which conducted the philosopher to the supposed discovery. (§ $5\frac{1}{2}$, α -f.) Our argument, however, will be particularly with Professor Lehmann, who has gone more fully than Bernard into many important bearings of the question.

1031, b. Now, in respect to the production of bile, Professor Lehmann is a perfectly orthodox Physiologist; but, apparently, only so because the reagents employed in Chemistry have not yet transformed the constituents of blood into any of those so-called proximates which they so readily effect in the bile. (§ $54 \ a$, 1029, 1030.) Doubtless, however, when that shall have been consummated, as is not unlikely to happen, the liver will lose its isolated rank in Physiology, and fall to the level of

other "strainers." Thus, our Author:

"In passing to the consideration of the individual biliary substances, and inquiring which of these exist preformed in the blood of the portal vein, we find that none of the most essential constituents of the bile can be detected in it." "The error of supposing that biliary substances have been demonstrated in the blood of the portal vein by means of sugar and sulphuric acid, arises from the similar reaction which Pettenkofer's test gives with olein and oleic acid."—Lehmann, ibid., vol. i., p. 480. Our author says, also, that "During the slow passage of the blood through the liver, it undergoes such important modifications, that a mere filtering off of certain constituents of the blood through the liver is not to be thought of." And so Müller, § 42, and Mülder, § 350\frac{3}{4} e, and Liebig, § 53 c, 409 b.

It is even denied by Kane and others, that the bile is absorbed into the blood in cases of jaundice—only the coloring matter. "The problem," say Becquerel and Rodier, "as to whether the bile passes into the blood has occupied the attention of Chemists as well as Physicians, but it does not appear to have been thoroughly solved by either."—Bec-QUEREL AND RODIER'S *Pathological Chemistry*, p. 239. London, 1857.

As to lactic acid and urea, Lehmann declares that "The recognition of lactates in healthy blood is just as difficult or impossible as that of urea in the same fluid."—(Ibid., vol. i., p. 96.) The supposed pre-existence of Liebig's "important instrument," protein, in the blood (§ 18 c, 409), and of the great digester, pepsin, also, is abandoned; which, indeed, may

be equally said of most other organic products.

Now, in these facts which Chemistry has been gradually learning in its career of "experimental philosophy" it should recognize a very strong analogy in proof that the formation of all the secreted products of an organic nature, and in the natural condition of the body, depends upon the organs by which they are elaborated, and that they had no pre-existence in the blood. The various modifications which lymph undergoes, as deposited by the most simple structures in different parts of the body, reflects a flood of light upon our subject (§ 408, 409 e-h); and I may appeal to Liebig for a great general law which carries our analogy through all organic nature (§ 42). The analogy, however, supplied by the simple tissues should be at least conceded to the glandular organs, since it is here corroborated by a strict analogy of structure; and where chemical reagents determine from the blood the same so-called proximates which they are capable of deriving from the secretions, these supposed proximates should be regarded equally as artificial transformations (§ 43, 53 b, 54 b, 417, 1030), and Organic Chemistry should cling to catalysis as its only consistent and dignified ground (§ $350\frac{3}{4}$ a-g, 409 j). But such has never been the philosophy of Organic Chemistry. It discards, ostensibly, the organic force, or vital principle, or plastic power (for they are convertible terms), while there is scarcely a modern treatise upon chemical physiology which does not invoke the aid of that power in its lucubrations upon the phenomena of life, and then with senseless ingratitude casts it away as a phantom of the imagination; though it should be excepted in behalf of Lehmann that he is consistent throughout in disclaiming all connection with any thing but the mere properties of dead matter. It is not, therefore, remarkable that, when these philosophers manufacture sugar or urea out of the blood they should neglect their pronunciation relative to the constituents of the bile. Our able Author is of this number, although he finds much difficulty with diabetic urine. But this is partially overcome by the assumption that "no one can doubt that it is, for the most part at all events, derived from vegetable food."-(LEHMANN, ibid., vol. i., p. 259.) And "M. Mialhe, especially, believes that the formation of sugar can not be independent of a saccharine or amylaceous diet."-(BECQUEREL AND RO-DIER, ibid., p. 249.) No one, however, acquainted with the literature of medicine is ignorant of the fact that the saccharine matter in diabetes is said to be often as abundant when the patient subsists as exclusively upon animal as vegetable food, and that there are those who have considered a vegetable diet most conducive to the disappearance of saccharine matter in diabetes. (See Essay on the Philosophy of Diabetes, in Medical and Physiological Commentaries, vol. i., p. 674-682 (1840), where this ground is considered, and where the Author anticipates the ultimate failure of detecting sugar and urea in the general circulating mass of blood, in opposition to the statements then in vogue; or, as Christison had it, the blood is sometimes "loaded with urea." Also, § 1007 c).

Nor can the laboratory approach an intelligible answer why such a profusion of saccharine matter is elaborated during lactation, unless it be allowed to be the product of the mammary gland (§ 424). Whence comes this substance in the nursing-mothers of the human race that are wholly restricted to a meat diet, as in dyspeptic troubles, if vegetable food, as is admitted (ut supra), must yield, "for the most part at all events," that substance to diabetic urine? Or where shall we look for it in the nursing-mothers of the strictly carnivorous tribes? Will the laboratory answer why saccharine matter is not accumulated in the blood when lactation is suppressed? Or if, according to Bernard, sugar be found throughout the circulating mass of blood during digestion, why is not some small part of it at least "strained off," as in diabetes? According to this Philosopher, when it gets involved in the circulating mass, it must be an effete substance, since it is said to be generated by the liver to be extinguished in the lungs for the uses of the general economy. Nor will it do to assume that the quantity is too small; for it appears to be far more easy of detection by Bernard in the blood of the renal arteries than urea can possibly be under any circumstances. The fact, therefore, contradicts the experiments. Moreover, is it probable that the same disposition would be made of sugar by the lungs when circulating in arterial blood as when presented to those organs by the venous blood of the hepatic veins? (§ 409, e.) No incongruous hypotheses will answer here; and it is evident that the Chemist would avoid the inquiry. (See Lehmann, ut cit., vol. ii., p. 344.)

It is true, it made no difference with Cl. Bernard (who, doubtless, had the foregoing facts before him) whether animals were fed upon vegetable or animal food. He was always sure to find sugar somewhere between the liver and the lungs, or, at all events, in the supposed laboratory

itself. But we will hear him:

"We fed a great number of dogs, at the College of France, during six or eight months exclusively with meat. The animals being then killed, 1.90 gr. of sugar was found in the liver, and this is as large a proportion as is found in dogs that have been allowed a mixed diet (l'alimentation mixte)".—Bernard's Leçons de Physiologie Exp., appliq. à la Médicine, p. 69. 1854-5.

Bernard also allows the fact (important in its connection with the foregoing), that long abstinence occasions an entire failure of the production of sugar. Nor did he find it in any of the cases beyond the precincts of the liver, which farther embarrasses the phenomenon of lactation in carnivorous animals, and of diabetic sugar as it presents itself in man when subsisting upon animal food alone. Moreover, Bernard failed of detecting sugar in the liver of some diabetic patients, which leads Becquerel and Rodier to say that,

"The theory of Bernard, although bearing the stamp of probability, presents, nevertheless, certain difficulties which farther experiment can alone remove. As long as the absence of sugar in the livers of a certain number of diabetic patients remains unexplained, his theory must be regarded as incomplete."—Becquerel and Rodier, ibid., p. 249.

Nevertheless, there appears to us no difficulty in accounting for the production of sugar either by the mammæ in lactation, or by the kidneys in diabetes, although the subjects subsist exclusively upon animal food, or be subjected to prolonged abstinence. Glucose or grape sugar, which is said to be identical with diabetic sugar, consists of twelve atoms each of carbon, hydrogen, and oxygen. These are the main constituents of the blood, whatever the diet; and if the Chemist fail of fabricating sugar out of the blood or liver after prolonged abstinence, it does not show in the least that it may not be generated by some part of the living organism. But it does show that Organic Chemistry is at fault in its premises when it confounds the living body with a chemical apparatus. Well, therefore, has it been said, when chemically considered, that

"M. Bernard, while asserting that the liver may secrete sugar without the ingesta of such alimentary substances as are usually considered necessary to its formation, nevertheless admits that prolonged abstinence may even produce complete disappearance of the sugar. This result—the formation of sugar without constituent materials—is the most unacceptable portion of his theory, and new experiments are requisite before it can be satisfactorily proved."—Becouerel and Rodier's Pathologi-

cal Chemistry, p. 248.

Nor is it a less interesting feature of the subject, that the liver should be regarded as the producer of saccharine matter in virtue of its organization and properties, both by Bernard (ut cit.) and by Lehmann (ut cit., vol. i., p. 257, 624; vol. ii., p. 344), as, also, of the bile, while the mammary gland in fulfilling its wonderful final cause, alike in all its variety of structure, and the kidney in a special form of disease, are degraded to the mere mechanical office of filtration. (§ 408, 424.) I need not speak of the dormant condition of the former gland in all mammiferous animals in the absence of maternal relations, but may say that, according to Lehmann, "in a normal state it is probable that no sugar finds its way into the urine" (§ 829), and that "it is only seldom we meet with saccharine matter in other diseases than diabetes;" and even "in the blood of diabetic patients, I never could find," says Lehmann, "more than 0.047 p. m. of sugar;" (ut cit., vol. i., p. 257, 623.) Becquerel and Rodier go farther than this:

"The only disease," say they, "in which it has been found is diabetes; and in this its presence has given rise to so much difference of opinion, that doubts remain in the minds of many respecting it. It is certainly, however, found in no other disease. Among the thousands of specimens of serum which we have examined, it has never been once detected; nor has any other Chemist alluded to its presence except in diabetes. But even in this disease, its existence in the blood has been considered doubtful, and is even denied by some Chemists—Guendeville, Vauquelin, Segelas, Wollaston, and Henry." And, as to the test of light, "it is as the result of upwards of a thousand analyses of the blood by means of the polarimeter, that we feel authorized to affirm, that if sugar exists in the blood of persons suffering from other diseases than diabetes, the fact is extremely rare and exceptional."—Becquerel and

Rodier's Pathological Chemistry, p. 71, 72.

It appears, therefore, that Organic Chemistry has receded to about the conclusions which we adopted upon physiological grounds seventeen years ago, and fortified by the observations of a distinguished Chemist of that day, whom we quoted in the *Medical and Physiological Commentaries* (vol. i., p. 674), in the following manner, and to which we now refer in behalf of vital solidism. Thus, the Commentaries:

Mr. Kane has stepped forward in behalf of the dignity of chemical science, and it is to such philosophers that an "acknowledgment" is due from Physiologists. In respect to the blood of diabetes, he remarks,

that, "the results of these analyses show that in diabetes, the relative proportions of the organic principles remain quite within the limits of the composition of the blood in *perfect health*. In fact, the blood cannot, as far as these experiments go, be considered as at all affected in this distressing malady."—KANE, in Dublin Journ. of Med. and Chem. Science,

vol. i., p. 24 (Compare with § $5\frac{1}{2}$ a, 847 a, 1007 c).

But, however this may be, it cannot be doubted that, in the multitudinous experiments which are made with chemical reagents, some process may be found which is capable of generating from the blood a transformation more or less analogous to saccharine matter. Upon the whole ground, also, of the chemical philosophy of organic products, no objection can be alleged against our conclusion; since, if the formation of sugar in the vegetable and animal organism be a chemical phenomenon, nothing would be more likely than its manufacture by the Chemist out of other organic compounds having the requisite elements, though this conclusion is very far from showing the accuracy of the former. But, it is far more important to science and philosophy, and especially to practical medicine, that we have Lehmann's authority for saying that these analyses cannot be trusted. (§ 1029, 1030.)

§ 1032, a. Let us now consider the question in connection with urea. We have seen that Lehmann states that "the recognition of lactates in healthy blood is just as difficult or impossible as that of urea in the same fluid" (§ 1031); and he remarks that "many Chemists have long sought in vain to detect urea in normal blood; Simon believed that he had found it in calves' blood, and Strahl and Lieberkuhn, and recently Garrod, maintain that they have detected it in human blood. Without doubting the correctness of these Chemists, it is only recently that I have been able to convince myself by decisive experiments that urea is present in normal blood."—(Lehmann, ut cit., vol. i., p. 153.) But may it

not have been an artificial product? (§ 417, 1029.)

Becquerel and Rodier remark that "urea probably exists in healthy blood, but in too small a quantity to be discovered by chemical analyses." This conjecture arises from the supposed discovery of urea in the blood by Prevost and Dumas after extirpating the kidneys of animals, and from its discovery by some Chemists, "chiefly in Great Britain," in Bright's disease. But Becquerel and Rodier have failed of detecting it

in that affection. The question is then propounded—

"Does the same thing occur, however, when, from any other cause, the urinary secretion is greatly diminished, as in retention of urine, and in the various diseases to which the kidney is liable? On this subject, analysis is as yet silent; and here, as in Bright's disease, much remains to be done." (See cases of both in Med. and Phys. Comm., vol. i., p. 601, n.).

As to the prevailing prejudice which often refers cerebral disorders to

a urea-diathesis, these Authors remark that

"It has indeed been asserted that when the accumulation (of urea) became considerable, we might attribute to it those cerebral symptoms which are commonly met with in the last stage of many renal diseases. This may possibly be the case, but it altogether remains to be proved." And, as to kiestine, which has become ingrafted upon the philosophy of pregnancy, it is now said by Becquerel and Rodier that "this discovery is a pure illusion."—Becquerel and Rodier that "this discovery is a pure illusion."—Becquerel and Rodier, ibid., p. 70, 353. (See Medical and Physiological Commentaries, article Humoral Pathology, where objections are brought against the supposed absorption of urine in cases of suppression.)—Note Z p. 1130, an explanation of uramia.

But Lehmann has finally succeeded in elaborating urea from healthy blood, and therefore again violates the analogy both of function and organization which he ascribes to the liver, of which he affirms "that a mere filtering off of certain constituents of the blood through the liver is not to be thought of;" and although, "like Becquerel, he has failed in establishing the fact that there is an augmentation of urea in certain forms of disease, although English physicians have shown an inclination to assume a urea diathesis" (uramia), yet, having finally elaborated urea out of the blood, he neglects not only his own forcible analogy, but the fact that urea is readily formed in the laboratory, in a variety of ways, especially by transformations of cyanite of ammonia and of urine; and, therefore, not only overleaps the clearest induction from the premises that chemical reagents may, at least, accomplish the same artificial result when brought to act upon blood (§ 53, c; Liebig), but, in common with other distinguished Chemists, is led to regard the kidney as a mere strainer. (§ 409 e, 422, 423.) Whether, however, "catalysis," or the philosophy of "strainage" be adopted, before either can prevail beyond a mechanical age, they must answer us, in some slightly intelligible manner, how it happens, in conformity with the known facts of either Chemistry or Mechanics, that the urine undergoes such sudden augmentations from the operation of fear and from the contact of cold air with the surface of the body ($\S 246, 422, 892\frac{3}{4}$); and why, also, the milk is liable to sudden and remarkable changes from mental emotions. But this would be of very little importance were it confined to the source in which it originated. Our Author, however, has contributed a good part toward assigning to the liver its proper rank in nature—abating the catalytic doctrine of its modus operandi; and it may therefore be reasonably expected that the time is near when the contrast in function between the liver and testis on the one part, and the mamma and kidney on the other, as now presented for the government of medical philosophy, will turn the attention of Physicians from the dogmas of the Laboratory, and the analogies drawn from "Strainers," to the study of living nature, and end in restoring Physiology to its proper cultivators. (§ $4\frac{1}{2}$ d, $376\frac{1}{2}$, 409 i,

1032, b. It is true, the kidney is an organ of excretion, and may, therefore, eliminate any foreign matter from the blood, though not by filtration. We do not deny that effete organic compounds, even sugar if it stray through the lacteals in morbid states (§ 192, 277-295, 826-827), may be eliminated more or less unchanged by the kidneys; though, for reasons already assigned (§ 38-51, &c.), this fact cannot be satisfactorily determined, either as to the blood or urine, by chemical reagents; and for this, too, we have the authority of Lehmann, Liebig, and Mülder. (§ 42, 53 c, 450^{3}_{4} e, 409 j, 1029.) But urea is not introduced from without, and holds the same relation to the urine as cholesterin and the resinous principle do to the bile, if we allow these and urea to exist naturally in the conditions in which they are presented after the application of chemical reagents. (§ 53 b, 417 a, 1029, 1033.) But it is quite otherwise, in the former respect, with saccharine matter, which abounds in vegetable food. If this, therefore, were not destined for the nutrition of animals, and underwent no change in the process of digestion, it should, like any other foreign substance, be freely eliminated, in the same or some modified condition, by the kidney. But the general failure of detecting it in the circulating mass of blood, in connection with the great

amount which is appropriated by man and herbivorous animals, and its great abundance in milk and diabetic urine, and its absence in all but diabetic urine assure us of two facts, namely, that it does not enter the circulation unchanged, in healthy states of the body (§ 192, 277-295, 826-827), and that the mammary gland is capable, under certain very remarkable physiological influences, and the kidney in a special form of disease, of recombining its elements into saccharine matter, whether those elements exist in intimate union with the blood, or be derived from the disintegration of the tissues. But in morbid states of the digestive organs, as always attend diabetes, it might be supposed that saccharine matter would be readily taken up by the lacteals, when, like any other effete substance, it should be excreted by the kidney in some shape or other (§ 192, 277-295, 426, 826-827). It is certainly a remarkable coincidence that the mamma and kidney should, in special conditions of those organs, and in such conditions only (§ 424, 426, 427), be alike capable of forming saccharine matter out of the blood. But this is entirely less remarkable than the double function assigned to the liver of generating bile and sugar for important uses in the animal economy. Nevertheless, while the former circumstance disproves the physical rationale of filtration, it is more improbable that the mamma and kidney, under those special conditions, and those only, should alike become "strainers" of a substance which is admitted to exist in a greatly insufficient amount, at most, in the circulating mass of blood. It is also, I repeat, a far more probable hypothesis, that the kidney should produce sugar out of certain elements of the blood in that remarkable affection known as diabetes mellitus, than that the liver should not only perform habitually the two great functions of generating bile and sugar (the one for important uses in digestion, and the other for nutrition), but that its saccharine function should be abnormally increased in diabetes and also when required by the exigencies of lactation, and then applied to that specific purpose—and when, also, there is a special gland provided for the generation of milk.* Let it be considered, too, that the formation of sugar by the mammary gland has no reference to the internal economy, but, totally unlike the uses attributed to sugar as supposed to be generated by the liver, it is destined to undergo the same process of digestion as the sugar which is supplied by plants. Now, these are principles which can be set aside only by absolute demonstration (§ 1086).

Moreover, in diabetes the condition of the urine is remarkably altered in other respects, especially in regard to quantity; and the quantity alone denotes an essential change in the natural function of the kidney. And it may be said farther, for the sake of the analogy, that in morbid conditions of all organs, indeed of all parts of the body, and according to the nature of the malady, the secreted products are diverted from their natural character. This is even strongly exemplified in the various phases of common inflammation, and not less remarkably in the specific forms of that disease (§ 733, 740–741, 653 c). And again, I say, since it is allowed that sugar is not absorbed by the veins or lacteals, it would be clearly a foreign substance if intermingled with the circulating mass of blood, and would be at once excreted by the kidneys, and, therefore, in lactation, were the sugar generated by the liver, it should not go by way of the mammary gland. It appears to me that Nature is not so

^{* &}quot;Crystallized milk-sugar has exactly the same empyrical formula as anhydrous glucose, so that it therefore contains equal equivalents of carbon, hydrogen, and oxygen,"

inconsistent as to justify the supposition that she has provided against the entrance of sugar, unchanged, into the general circulation, and at the same time has constituted the liver, or any other part, with a view to the reproduction in the torrent of the blood of what she has so carefully excluded in her arrangements for supplying the requisite means of nutrition—and this, more especially, as she has provided the mammary gland for the generation, in part, of saccharine matter, though not to be confounded with the torrent of blood, but to undergo transformation in the stomach.* Or why, again, has she so completely provided for the metamorphosis of sugar in the alimentary canal, if it is to be at once regenerated by the liver (§ 409, b-411); and thus, also, impose upon this organ, in violation of all her analogies, two perfectly distinct functions for the generation of products of fundamental uses in the animal economy, and whose uses, respectively, are perfectly distinct from each other? It will be no answer to say that, in ordinary states of the body the hepatic sugar is at once disposed of in the lungs; for, besides the fundamental objections already made, this hepatic sugar is supposed, in lactation, to be partly diverted from its great physiological purpose to supply means of nutrition to an external subject, which has no more relation to the individual than the plant has to the stomach! Or, if we glance at diabetes, there is the same inconsistency there. And yet another objection may be seen in another violation of analogies, in supposing that a glandular organ pours into the torrent of the circulation one of its most important products, while another not less specific takes the ordinary course toward open surfaces (§ 417).—Notes N R pp. 1121, 1123.

Cl. Bernard appears to be aware of the inharmonious nature of the new function which he has assigned to the liver with that of the production of bile. "Is it probable," he says, "that the albuminous substances of the blood, on reaching the hepatic cells, separate into two compounds, a hydrocarbon, destined to form sugar, and a nitrogenous one for bile? If this were so, these two compounds would be formed at the same moment." Bernard thinks, therefore, that "his experiments seem to denote that the formation of sugar and bile does not take place simultaneously, but that they alternate with each other." (Leçons, ut cit.) But this will not correspond with the consistent philosophy of organic life. It is also worthy of remark that Bernard's explanation of the disposition of the supposed hepatic sugar in the lungs is very unsatisfactory, even in a chemical sense; and, farther, that there is scarcely any agreement between him and Lehmann as to the uses of sugar in the animal

economy (§ 83, 316, 409 f, i, 419 b, 423, 424).

I shall now introduce a paragraph which denotes the course of argument pursued in the Medical and Physiological Commentaries upon the

questions before us:

When the secretion of milk is suppressed, I have there said, do we find that the saccharine matter is accumulated in the blood, or do we find a trace of it there, or is its secretion "replaced" by any other part? Or, shall we go on believing with Puzas, Leveret, Sauvages, Van Swieten, Selle, Astruc, Raulin, and many others, that it is generated by the legs, and forms the proximate cause of phlegmasia dolens? Or, when the secretion of bile is suspended, do its peculiar constituents appear in the blood, or their elaboration devolve upon any other part? We have shown that it is not so. Would you believe the oath of any one who might swear that he had detected semen in the blood, or in the saliva of

^{*} Notwithstanding the exigency of digestion, even educated physicians (except in physiology) apply butter, &c., to the skin as a means of nourishment (§ $1088\ b-d$)!

a female? And yet it is affirmed to exist in the blood. (See note. p. 589. Also, this work, § 83, b, note.) Shall we admit that the virus of the rattlesnake, the viper, the bee, &c., exists in the blood? If the viper and rattlesnake die after the removal of their venom-glands, it is far from proving that it is in consequence of an accumulation of their specific virus in the blood. It is the same logic here as it has been with urea after extirpating the kidneys. Do we find the peculiar odor of the skunk, of the beaver, of the musk, &c., in the blood? Thus might we go on with a thousand different formations, which, if admitted to exist in the blood, would, of course, assign to this fluid as many component parts. But if, on the other hand, it be absurd to suppose that the latter formations do not depend upon their peculiar emunctories, why is it not equally so to imagine that animal sugar, urea, or cholesterine, &c., are merely strained off from the blood? (§ 409, e.) Finally, as to urea, about which humoralism has been so much concerned in the philosophy of diabetes, we may say, that Le Canu, whose analysis of the blood is admitted to be the best, agrees with former Chemists in denying its natural existence in that fluid.—Med. and Phys. Comm., vol. i., p. 680. 1840.

§ 1032, c. If, however, the validity of the experiments by which saccharine matter and urea are said to have been obtained by analyses of the blood, and of other parts, be admitted, there is not much difficulty in interpreting the supposed results in conformity with a standard supplied by "experimental philosophy"—not even the curious phenomenon declared by Bernard of the existence of sugar in all parts of the circulation during digestion, but its subsequent limitation to the blood between the liver and the lungs. (§ 48, 49, 53 c, &c., Liebig; 350\frac{3}{4} e, f, Mülder;

1029, Lehmann.)

The blood is so constantly fluctuating in its effete materials (§ 426, 427), that they may be regarded as taking an important part in the transformations, either contributing directly to the artificial formation, or exercising predisposing affinities upon the elements of the blood, when chemical reagents are brought into action upon this fluid (§ 6, 54 a); and, if we now consult the foregoing references, we shall find the most eminent Chemists virtually coinciding in this opinion. But I may quote the more specific, and later authority of Lehmann, which I shall do in the language of a Reviewer, for the sake of some other statements which

occur in the same connection. Thus:

"It is a doctrine generally accepted by the Physiologists of the present day, that the glandular organ furnishes nothing to the secretion, but that its tissue (or, at all events, certain of its cells) exerts a catalytic action on the elements of the blood as it traverses the organ. In accordance with this view, Lehmann has afforded us a very satisfactory explanation of the origin of the sugar in the liver. On comparing the composition of the blood of the portal and hepatic veins, he found that the saccharine blood of the hepatic veins contains less fibrin and less hæmatin than the non-saccharine blood which enters the liver by the portal vein. He then proved, by a very logical CHEMICAL PROCESS, that pure crystallized hæmatin might be resolved into glucose [grape sugar] conjugated with a nitrogenous substance," &c.—British and Foreign Med. Rev., Jan., 1857, p. 32. New York.

Now, it is true that this experiment is against our purpose, excepting in the important fact that it is supposed that blood, in certain conditions, may be chemically transformed into sugar. But how far is the experi-

ment reliable as to the distinction which is made between hepatic and portal blood (§ 1029)? Let us hear Bernard;

"Since the publication of his Leçons, Bernard has been led to give up Lehmann's explanation, and has been driven to the belief, from certain experiments which he has recently made, that it is not in the blood, but in the HEPATIC TISSUE itself, that we must search for the substance which precedes and directly gives origin to the sugar."—British and Foreign Med. Rev., ibid.

Our interpretation will also readily explain the reason why saccharine matter, or something analogous to it, may be made out of the hepatic blood, or out of the liver, when it has not been produced, or but in a minute quantity, from portal blood. In the one case the requisite conditions are present; in the other they are not. This is obvious enough from the quantity of bile elaborated from the portal blood (§ 417).

Again, this kind of "experimental philosophy" will explain the reason why, according to Vernois, "sugar may be found in the liver of the fectus and not in that of the mother, and vice versa;" and why it is found in the liver particularly after respiring an irritating vapor, which, through the reflex action of the lungs, modifies the whole sanguiferous function, and consequently the condition of the blood. Associated with this there may be something appertaining to the liver which may often enable chemical reagents to effect a transformation analogous to sugar. Again: if such be the philosophy, we should probably find the Chemist often failing to produce sugar from the liver in various conditions of disease. Accordingly we learn from Becquerel and Rodier that "in 140 cases, wherein the nature of the disease was noted by M. Vernois, he

only found sugar fifty-six times."—Ut cit., p. 247, 248.

§ 1032, d. As the variety of means which have been employed to increase the supposed normal proportion of sugar in the blood, and the artificial production of diabetes, in no respect affect our conclusions, it is unnecessary to speak of them. Our interest lies in the great physiological problems alone, under the direction of the leading facts. But I may say of Bernard's experiment of producing saccharine urine by pricking the floor of the fourth ventricle between the roots of the pneumogastric and auditory nerves, that it is not only an elegant exemplification of the wonderful mysteries of the nervous system in its influences upon organic functions, especially so in connection with the inductive process by which he arrived at the experiment, and should admonish him, profoundly, of the fallacious nature of his chemical and mechanical doctrines of life, but that it demonstrates a direct influence upon the functions of the kidney which places the mechanical hypothesis of "strainage" upon its proper footing. It is in vain to assume that this influence was exerted specifically upon the liver, and that that organ was thus stimulated to an extraordinary production of sugar; for the condition of the kidneys was not affected alone in the elimination of sugar, but in two other and opposite respects, according to the precise place in which the floor of the fourth ventricle was pricked between the origin of the nerves. In one place the urine would be increased in quantity, and yielded an abundance of albumen: while a little variation of the place of puncture rendered the urine small in quantity, and restricted the organic matter to sugar alone. (BERNARD, Legons, &c., p. 339-340.) Moreover, the kidneys and ureters were quite as violently affected by this prick as the capillary circulation of the abdominal organs, while the vessels on the surface of the liver "were more apparent than natural." The whole capillary system of other parts of the abdomen was thrown into a state of great activity and engorgement, and I shall quote the statement in a note* for the purpose, also, of showing how remarkably the vascular system may be affected by apparently the slightest impressions upon the nervous centres, and variously, too, as the impressions may be a little varied (ut supra), and to show, moreover, the absurdity of referring the physical products to the united agency of the nervous power and the chemical forces, and how great the fallacy of expecting to give direction to practical medicine by any analyses of the blood or secretions while they are unceasingly changing in disease through influences propagated by the nervous power (§ $5\frac{1}{4}$, e). Nor will the reflecting mind fail to observe the vast contribution which this experiment makes to the incalculable importance of those by Wilson Philip, as herein recorded, nor how forcibly the experiment confirms the applications which I have made of the English Philosopher's (§ 476-494, &c.).

But again: if it be assumed that the influences were exerted, in the experiment, upon the liver, and that the kidneys merely "strained off" the redundant sugar, how does it happen that no sugar ever appears in the urine during the digestion of food, when, as affirmed by Bernard, it is found throughout the circulating mass of blood? Why never found in the urine in any hepatic affection, and never in any other disease than diabetes? And what shall be inferred of the pathology of diabetes, or of the indications of cure as supplied by Organic Chemistry, when we contemplate the successful treatment, by bloodletting, of the remarkable case recorded in § 1007, c?—Note Z p. 1130, on uramia.

Since the foregoing was written, information has reached us that later observers have shown, that, whatever may be the influences exerted by the injury of the fourth ventricle, as it respects the hepatic blood, they have no bearing upon the functions of the liver, but of the lungs. From these observations it would result that the special condition of the hepatic blood is owing to some modification of the respiratory function, which is rendered farther probable by the injury being inflicted at the origin of

the pneumogastric nerve (§ 461).

1033, a. After the remarks in the foregoing section (§ 1032), and upon the hypothesis that it is truly sugar which is discovered in blood by the reagents (tests), or whatever compound it may be, it must be conceded in behalf of the hypothesis, that the same apparent result is brought about by different modes of proximate analysis. But even this coincidence neither establishes the certainty that the products consist of sugar, nor render it unquestionable whether any two of them are alike. (§ 54, a, b.) It is but a guess, liable to the doubts which are so forcibly expressed by Professor Lehmann in sections 1029, 1030. Nevertheless, in a physiological sense, it is the most involved and important inquiry which Organic Chemistry has yet presented, and hence the space which is here allotted to it. Should this persevering Offspring of the inorganic world succeed, in connection with experiments upon living nature, in establishing the supposed double function of the liver, it will have contributed a But such are the complete contradistinclarge service to Physiology.

^{* &}quot;Quand, après avoir piqué chez un Chien ou chez un Lapin l'origine des pneumogastriques, nous lui avons ouvert la ventre au moment où la surexcitation portée sur la foie présentait son summum d'intensité, nous avons vu qu'alors il y avait une plus grande activité de la circulation abdominale, le système capillaire était gorgé de sang, et les vaisseaux de la surface du foie plus apparents qu'à l'état normal. Les reins sont alors eux-mêmes très surexcités, les uretères sont tres irritables; il suffit de la toucher avec la pointe d'un bistouri pour les voir se contracter energiquement."—Bernard, Leçons, &c., p. 331. 1854-55.—See Budge's Exp. § 494 e, and § 635.

tions between organic and inorganic beings, that it may be safely concluded that it can go no farther than to distinguish the difference between the physical constitution of one substance and another. Here it ends, and here the vitalist takes up the result and carries it into the profound labyrinth of organic life. Even so Liebig, § $18\ c$, 42, $53\ c$, 59, $64\ e$, 350, nos. 59, 79. (Also, § 5, 6, $53\ b$, $222\ b$, 351, 362, $376\frac{1}{2}$, $409\ j$, 417, &c.)

In the mean time, as an appendage of some moment to the foregoing discussion, and that it may be compared with the extracts from Lehmann's work, in sections 1029, 1030, I shall now state, as an example of searching for sugar, an unsuccessful process observed by Lehmann for

detecting its presence in the portal blood of horses:

"The blood, after being neutralized with dilute acid, and treated with four times its quantity of water, was coagulated by heat, the expressed and filtered fluid was evaporated, the residue extracted with spirit of 85°, and the spirituous fluid precipitated by an alcoholic solution of potash. The portion insoluble in water was mixed with a little water, filtered, treated with dilute sulphuric acid, for the purpose of effecting the metamorphosis of any dextrine that might be present, and then examined for sugar."!—Lehmann's Physiological Chemistry, vol. ii., p. 391.

There is also the celebrated test known as Barreswill's solution, which consists of "carbonate of soda (in crystals) 40 parts; bitartrate of potash 50 parts; caustic potash 40 parts; distilled water 400 parts. Make a solution, and add the following: Sulphate of copper 30 parts; water 100 parts. Filter the two solutions when mixed. This solution, when added to a liquid containing glucose, gives a reddish precipitate of re-

duced copper."

Another chemical test is that of caustic potash, "a fragment of which, added to serum containing glucose, gives an albuminous precipitate of a brownish color, due to the combination of albumen with ulmate of potash."

Becquerel and Rodier say, that the chemical processes relied upon are "almost exclusively" the last two—B. and R.'s Patholog. Chem., p. 72, 73. Lehmann commends Trommer's test, which consists mostly of caustic potash and sulphate of copper, but which has been disputed. "But if this test be not admitted," he says, "equal objections may be advanced against all the reagents employed in mineral chemistry; the application of most of them demanding more precaution and skilful manipulation than this test." He thinks well of the polarizing apparatus; says that "Pettenkofer's test is not available for the detection of sugar;" and he would not trust the fermentation-test, nor Maumene's. After mentioning these, and their attendant qualifications, we have the farther discouraging remark, that "all other tests which were formerly employed for the discovery of sugar are open to so many sources of fallacy, as compared with the methods we have already indicated, that we may pass them over in silence."—Lehmann, ut cit., vol. i., p. 251, 256.

1033, b. Now, all the foregoing (§ 1033, a) would be commendable, did it end, so far as Chemistry is concerned, with the experiments themselves; although, as we have seen (§ 1029, 1030), it can rarely supply any reliable ground for induction. But it is an example only of a vast amount of experimental Chemistry which has been carried far into the labyrinth not only of the physiological but morbid states of the body, and commended to Physicians under the illusory name of "experimental"

medicine."

But, suppose it to be all true, there never was and never will be a physician who will or can apply it in practice, very few who can understand it, no one qualified for the analyses, no time, in acute diseases at least, for inquiries so difficult and tedious, and no one who will fall into the absurdity of applying to a competent Chemist, if he can find one, to search for disease in morbid changes of the blood, or secretions, not even of the urine. In chronic affections, a few simple observations upon the latter, and which are alone reliable, will sometimes inform the physician of the presence of some unusual substances as the products of disease; but this knowledge can never aid him much in the treatment of the malady (§ 427). Take the strongest of all examples, diabetes mellitus; a knowledge of the existence of sugar in the urine has neither contributed to a knowledge of the pathology of the disease, nor given the slightest direction to an enlightened practice. An exclusively animal diet has not reached the pathological condition, and the sugar has gone on as usual whatever the food consumed. Nor is it any better with the "ureadiathesis," or with "albuminous urine," whether the latter respect the kidneys or dropsical conditions; but, on the contrary, it has led to many blunders between the presence of disease and the ingesta, or between one disease or another (§ 426, 427, 639, 673, 675, 679, 686 d). If the Physician rely upon these superficial and uncertain, or imaginary signs, if he have not the sagacity to discover the nature of disease through the ready and intelligible signs supplied by Nature, or cannot avail himself of experimental observations upon the effects of remedies which have been accumulating for ages, or be incapable of applying in practice the principles which have been founded upon these observations in their connection with other intelligible principles in physiology and pathology, his case is as hopeless as must be that of his patients (§ $5\frac{1}{4}$, f). And yet, it is a remarkable fact, that many medical Authors, who take the "experimental medicine" of the day upon trust, are vastly more certain of the accuracy of the experiments, and of their application to the healing art (and yet without applying them), than the very able men who have been employed long and assiduously in the inquiry. (§ 1065, b, c.)

It was but very recently that the Medical Profession in Europe and America calculated upon Morbid Anatomy as a grand basis for medicine, and the present writer took a long ground against it. And where is it now? Dissipated by Liebig as by an enchanter's wand. Where now is the so late "Numerical Method?" (§ 1006, a.) Swallowed up by the Laboratory. Where, the Humoral Pathology, which Andral reproduced and ingrafted upon Vital Solidism? (§ 819, &c.) Ingrafted upon Chemistry. Where the so late "experimental philosophy" which aimed at the causes and cure of human maladies by the introduction of poisons and remedial agents into the circulation of animals? (744.) "Given place to an 'experimental philosophy' in which organic life has no participation" (§ $5\frac{1}{2}$ a). Where the "division of labor" in the fragmentary system of "specialities?" Concentrated in the hands of Organic Chemistry (§ 960, c). Where, I ask, are the memories even of those so recent as Hunter and Bichat? All buried in the common Cemetery. Where, in brief, is Organic Life? Echo answers, extinguished by the Laboratory (§ 695-709. See, also, the Author's Essays on Morbid Anatomy, and on the writings of M. Louis, in Medical and Physiological Comment-

§ 1034. Finally, in the discussion of controverted questions between

the Physiologist, as he looks upon animated nature in its healthy and morbid aspects, and the Chemist, who is, or should be, concerned alone with dead matter, it is sometimes difficult to maintain a perfect moderation of style when the Laboratory becomes dogmatic, and especially when exclusive (§ 1, b, 350, Mottoes). And I may be now permitted to at least correct a misapprehension of Professor Lehmann's, who, in the seclusion of the Laboratory, like all others of the same laborious and abstract pursuits, is evidently uninformed of the doctrines of the vital Physiologist, or does him an injustice which I should be unwilling to surmise. I allude to the following paragraphs, although there is much more of the same nature:

"We have not hesitated to avow that we have assumed a thoroughly radical point of view in reference to specific vital phenomena and vital forces; for we cannot rest satisfied with the mysterious obscurity in which they have been artificially enveloped."

Our Author then proceeds to designate the Science of Life as a system of "metaphysicology," and to confound Physiologists with the "advocates of a romantic poetry of nature;" though, it is true, he had the encouraging success of Liebig before him (§ 350, Mottoes). Thus, our

Author:

"It would be well if these spiritualists would look down from the high stand they have chosen, and deign to believe that there are some among those experimentalists, who, clinging to matter, and gathering their facts with ant-like industry from the lowly earth, notwithstanding that they have long held communion with the poet-philosopher, Plato, and the philosophical natural inquirer, Aristotle, and have some familiarity with the Paraphrases of Hegel and Schelling, are yet unwilling to relinquish their less elevated position. If these happy admirers of their own Ideal had descended from their airy heights, and closely examined organic and inorganic matter, they would not have deemed it necessary to assume, that, besides carbon, hydrogen, nitrogen, and oxygen, organic substances must also contain an organagenium, or latent vital force, or whatever else they may be pleased to call it. Had they sought information from a Chemist, they would have learned that, when exposed to the clear light of rigid logic, there is no essential difference between organic AND INORGANIC BODIES. A Chemist, totally unacquainted with organic matter, would à priori have deduced all these incidental differences of matter from the doctrine of affinity and the science of stoichiometry, evolved from dead matter. (§ 1052.) However these advocates of a romantic poetry of nature may despise the swarm of industrious investigators, who are often unwearingly occupied for years together in endeavoring to collect a few firm supports for the great edifice of a true philosophy of nature, we do not despair of seeing our work rise in simple grandeur. more durable and lasting than these sophisms of natural philosophy, which, passing through ages, from Pythagoras and Empedocles to Schelling and Hegel, have, like the sand of the ocean shore, been alternately upborne by one wave and ingulfed by the next."—Lehmann's Playsiological Chemistry, vol. i., p. 33, 34.—See p. 157, § 350, mottoes h-l.

That this is not a hasty rhapsody appears from a *note*, in which our Author states that he had "expressed similar ideas in an Article which appeared in the 'Gegenwart.'" At another time, also, he caricatures the doctrine of vital solidism as "a belief in *supernatural* forces of mat-

ter."-Ibid., vol. ii., p. 380.

There is no doubt that our amiable Author (whom no one is disposed to disturb in his legitimate pursuit) is very correct as an expositor of the objects and opinions of Organic Chemists when he asserts their belief that "there is no essential difference between organic and inorganic bodies: "as, indeed, appears abundantly in these Institutes. It is, therefore, all a foregone conclusion with the Chemist, before he approaches the living being with acids, and alkalies, and metallic oxides, and retorts, and crucibles, that he will quickly "deduce all the incidental differences of matter (animate and inanimate) from the doctrines of the Laboratory as evolved from dead matter." Hence, it is evident, besides his affirmation, that our Author has deduced all his knowledge of Haller, Baglivi, Hunter, Bichat, Müller, C. Bell, M. Hall, Tiedemann, and other illustrious Physiologists of recent times, from what he has gathered from "the Poet-Philosopher, Plato, and the philosophical natural inquirer, Aristotle, along with the Paraphrases of Hegel and Schelling;" glancing, it is true, at their kindred, Pythagoras and Empedocles, but skipping over, even, such ultra "Spiritualists" as Hippocrates, Celsus, Galen, Aretæus, Avicenna, &c., from whose works he might have "deduced à priori all the incidental differences" between them and their modern Antitypes. ($\S 4\frac{1}{2}, 5-6, 189, 292, 334, 350\frac{1}{4}, 350\frac{3}{4}, g, 351, 360-364, 366,$ $376\frac{3}{2}$, $376\frac{3}{4}$ b, 744, 1006 a, 1029, 1030, 1075 b.)

Nevertheless, although our Author "cannot rest satisfied with the mysterious obscurity in which the vital phenomena have been artificially enveloped," and, although "a Chemist, totally unacquainted with organic matter, would à priori have deduced all these incidental differences of matter from the doctrine of affinity and stoichiometry evolved from dead matter," he is coerced, not unfrequently, to contradict himself (\S 626, b), and to admit, as in the following example, that the "incidental differences" relative to absorption alone have been altogether beyond any explanation in physics, which is apparently a very simple phenomenon compared with many other processes of life, even as it occurs in plants

(§ 1053). Thus, our author:

"If, however, we still continuously encounter a number of phenomena in the living body, which seem to be at variance with the endosmotic laws with which we are at present acquainted, and if many interesting experiments, as, for instance, those of Böcker, still appear to defy explanation by simple molecular action, this merely proves that we are still deficient in the physical knowledge necessary for the comprehension, in a physical sense, of the casual [!] connection of such phenomena." (See § 1052.) "We may, however, conclude, from the scanty facts before us, that the movements of soluble matter within the living organism, and more especially the phenomena of absorption, must be supposed to depend upon certain physical laws."—Lehmann's Physiological Chemistry, vol. ii., p. 376–399.—Also § 176 d.

And again, our Author, still forgetting himself, is at considerable pains in showing that "if zoo-chemistry ever fulfil its object, it must be by the joint aid of Chemistry and *Physiology."—Ibid.*, vol. i., p. 24. But how far our Author (and Liebig, who is of the same opinion) is qualified to reason upon the profound problems of life will sufficiently appear

from the following jumble:

"Weariness of the senses is the diminished impressibility of the nerves of sense, but its cause cannot reasonably be sought for in any other than a CHEMICAL CHANGE, experienced by the conducting substance of the

nerves. Such a chemical metamorphosis of the nerves of sense from external impressions can no longer greatly excite our astonishment, since we have witnessed the unexpected phenomenon of a picture produced suddenly, and as it were by magic, from the chemical changes effected by the rays of light on an iodized silver plate [!] Should we not be equally justified in saying that the iodized plate, which, after being exposed for a few seconds to a strong light, gives only faint and half-effaced images, is wearied like the return, when, after repeated and continuous perception of an image, it gives back only the faint outlines of the object?"!!

—Ibid., vol. i., p. 30. (Also § 349 e, 350½ n, p, 350¾ e, f, 350¾ e.)

But this is only an example of a vast amount of a corresponding nature by which I have endeavoured to show that Chemistry and Physiology are profoundly distinct from each other, and that when the Chemist departs from his legitimate pursuit to gather laurels in Medical Science, whatever may be his ability, he is acting the part of a mere Charlatan

 $(\S 376\frac{1}{2}, 626 b).$

Our Author takes it hard that Chemical Philosophers should meet with any opposition in their invasions upon Physiology and practical Medicine, notwithstanding his own declaration that they are not to be trusted in their organic inquiries (§ 1029, 1030). But since he indulges the illusion that none but the most imaginative have raised an obstacle to the ambitious career of Organic Chemistry, it is not quite apparent why our Author's self-complacency should have been so much disturbed as seems to be implied in the concluding part of a foregoing quotation (page 796). The capital error of our friends is forcibly presented in that extract—"Who are often unwearingly occupied for years together in endeavouring to collect a few firm supports for the great edifice of a true philosophy of nature," and which has been often the subject of comment by eminent Philosophers, as may be seen at pages 157, 173, § 350, Mottoes, h, i, k, l, and No. 97 of parallel columns.

Our Author's error, therefore, as will be readily seen, proceeds from an unceasing devotion to the phenomena of dead matter (\S 376 $\frac{1}{2}$), which, as a consequence, leads to a total disregard of all the facts which have been accumulated by the students of living nature, and an obliviousness to the grand consideration that even such students can have no just appreciation of the natural processes of animated beings unless also well skilled in Pathology and Therapeutics (\S 5 $\frac{1}{4}$ e, f, 5 $\frac{1}{2}$ a, 6, 53 c, 129, 134, 137 d, 151, 163, 165 b, 167, 191, 234–235, 237, 285, 303 $\frac{2}{3}$, 376 $\frac{1}{2}$, 376 $\frac{3}{4}$, 447 a, b, c, 516 d, No. 6, 676 b, 801 a, 819, 1006 a, 1029,

1030, 198, 640, 1060).

But our Author has now the consolation of knowing that he has achieved his object of convincing a multitude of Physicians ($\S 5\frac{1}{2}$, a) that they are worthy of his rebuke, and that the true philosophy of medicine can be acquired only through an implicit dependence upon the Laboratory of the Organic Chemist ($\S 376\frac{1}{2}$). Nevertheless, our Author is too shrewd a politician not to have observed the action which has been setting in against a pursuit in which the Physiologist and Physician have had no participation whatever; nor is he less aware of the causes. Lest the monopoly, therefore, should be lost, he deals a few blows upon the most submissive part of the Profession in this wise:

"Enthusiasm," he says, "in the cause of Organic Chemistry has degenerated among many Physiologists and Physicians into a *fanaticism*, which, even in the best cause, tends to invalidate a host of truths in its

endeavours to uphold a single fact (§ $5\frac{1}{2}$ a, 530).—Lehmann, *ibid.*,

vol. i., p. 1.

But, then, how will our Author compromise the trouble with this class of "Physiologists and Physicians," if "there is no essential difference between organic and inorganic bodies," or, especially, if "a Chemist, totally unacquainted with organic matter, would à priori deduce all the incidental differences from the doctrine of affinity and the science of stoichiometry, evolved from dead matter?" Our Author's entire work proceeds upon these premises, along with a profusion of ridicule upon the physiological doctrines of life and disease, of whose deductions from the phenomena of living nature, through a long course of ages, he is as profoundly ignorant (as he virtually admits) as he is able and accomplished in that mere physical department of science to which he has devoted his thoughts and his labors. Our Author, therefore, seeing the "handwriting upon the wall," as appears in preceding quotations (§ 1029, 1030), ventures the future upon denunciations of those whose peculiar province it is to unfold the Science which Nature has isolated from all others in its fundamental laws. But I ask our Author and others who have not been less vehement in unmannerly malediction upon all Medical Philosophers of the past, whether the phrensy of a morbid ambition is not most likely to react upon themselves? (§ 6, 3761.) And I put it, also, to Physicians, whether they will continue to follow the wake of Organic Chemistry, or assume the independence of thinking and acting for themselves? And here I shall take the liberty of repeating a passage from the Commentaries which covers a greater range of the fictions that have been substituted, in recent times, for philosophical medicine. The Author was referring, specifically, to M. Louis's attempt to prepare the way for his anatomical and numerical methods by proclaiming that "Medicine is now in its infancy;" while it is but just to the French Philosopher to say, that the German is more dogmatically abusive, in various parts of his work, of every Physiologist and Physician who has admitted "a vital force or whatever they may call it" (in our Author's language), from Hippocrates to the present day. The Commentaries thus:

"That the World should have passively acquiesced in this unreserved obliteration of all its medical knowledge and principles (executed, too, in no very gracious manner), was neither just to itself, nor watchful of its dignity. That it should have received the ostracism with a commendation proportioned to its abruptness and insensibility must remain forever the most extraordinary record of all human affairs; and, when after ages shall look back upon the present, groping its way in a midnight darkness of its own creation, and rejoicing, as it were, with the prattling "infancy" of a once noble and stupendous science, and witness, as its results, the experimental processes by which the new being was to be carried forward to maturity—the myriads of victims who furnished their quota to the morbid anatomist—the attempts at converting morbid into healthy blood by chemical agencies, first in a 'porringer,' and then, by analogy, up to the living organism—the conflict between the remaining disciples of Nature and the abuses of the Laboratory-the almost universal substitution of the forces of physics for those specific powers which had hitherto rendered Physiology and Medicine intelligible and consistent sciences, besides a multitude of other strange devices, contributed and cordially received from all manner of workmen, as choice materials for the new foundation-when, we say, after ages shall look back

upon this dark spot on the brightest escutcheon of the world, it must be regarded without sympathy, and as an act of voluntary humiliation ($\$376\frac{1}{2}$, 530, 819 b).—MEDICAL AND PHYSIOLOGICAL COMMENTARIES,

vol. ii., p. 684. 1840.

§ 1035. Although the foregoing review of Physiological and Pathological Chemistry may be unimportant to all but the present writer, he will, nevertheless, say, that personal considerations had nearly deterred him from making them. In all his writings he had regarded his position as so isolated, that he had not anticipated much sympathy and less encouragement, and he has, therefore, been agreeably disappointed in finding numerous and very able advocates, and by many unexpected and very distinguished honors that have been conferred upon him by the most renowned Medical Societies in Europe. These marks of recognition, he hopes of approval, have always awakened the most profound gratitude. But the more he has prosecuted his studies, the more impossible has he found it to modify his opinions on Medical Philosophy, and the more desirous has he become of submitting this enlarged experience to the judgment of mankind; and, although he is not unmindful that perfect independence is conceded to the Cultivators of science, yet he is most anxious to be just to those whose writings have proved to him a fountain of knowledge, and whose kindnesses have awakened the deepest sensibility. And, while thus employed in this very personal manner, he will not forego the gratification of uniting to that of the medical world his own admiration of the labors of Becquerel and Rodier, and particularly of those researches which are presented in their work on "PATHOLOGICAL CHEMISTRY IN ITS APPLICATION TO THE PRACTICE OF MEDICINE." The very flattering dedication to himself which occurs in the London edition of that work might, in connection with the considerations just stated, have prompted him to have still maintained the silence (unimportant to be sure) which he has for some time observed, did he not find in the work so great an amount of enlightened research, and which he can heartily commend to the American Medical Profession. It is, indeed, rather a system of practical medicine than what the Title imports. Its authors have been attentive observers of disease, and their valuable experience is presented in its direct relation to Pathology and Therapeutics. Their pathological chemistry of the blood is, also, but little liable to the objections so forcibly stated by Professor Lehmann (§ 1029), since it often extends but little beyond the specific gravity, and the proportions of water, globules, albumen, fibrin, and fatty and extractive matters, in different forms of disease, and their comparison with a normal standard. And, although these analyses advance our knowledge of pathological conditions, the present writer cannot but adhere to his opinion that the treatment of disease must turn essentially upon the import of symptoms and of remote causes, in connection with the principles which have been deduced from the phenomena of healthy and morbid actions, and from the results of hygienic and therapeutical treatment (§ 413-463, 639-709); nor has he any doubt that his Authors think so too. They belong to the school of Vitalists, ever designating the blood as the vital fluid, and quote, approvingly, from Simon's Animal Chemistry, the following enlightened opinion respecting fibrin, which stretches far into other great problems in vital physiology. Although stated as an abstract fact, it associates with itself the whole labyrinth of physiological results, and is unapproachable by chemical laws. Thus:

"The fibrin, in its normal physiological condition, is the result of the transformation of a certain amount of the globules. This transformation, which is of a vital nature, is due to the action of the oxygen of the atmosphere on the one hand, and, on the other, to the numerous reactions which take place during the passage of the blood through the different tissues and organs of the body. The globules, before being assimilated to these tissues, and thus contributing to interstitial nutrition, pass through a transition state, which is the fibrin (§ 42)."—BECQUEREL AND RODIER'S Pathological Chemistry, p. 105.

However much the writer may differ from the chemical school of medicine, his attention has been directed to their researches during the greater part of his professional life, and, he acknowledges, with intense interest and never-failing information, while he also commends to his medical class the same habits of inquiry. He had known nothing of the composition of organic nature, nothing of those elementary combinations which so forcibly distinguish it from the inorganic kingdom, and many other relative details, nor could these Institutes have been written, with-

out the revelations afforded by Chemistry ($\S 376\frac{3}{4}$, b).

PROGRESS OF PHYSIOLOGY.

STRUCTURE OF ORGANS.

1036. Many interesting disclosures have been recently made in the minute anatomy of some of the complex organs, and the microscope has been brought to bear advantageously upon the subject in connection with improved methods of minute injection. The structure of the kidney, whose rank in organic life I have advocated in foregoing sections (§ 417, 422–427, 892\frac{3}{4} a-c, 1032), has been subjected to much critical inquiry, and although the exposition of its elaborate organization call up an association with the most complex mechanism of art, it reminds us as little of "a strainer" as it does of a musical instrument (§ 1032). But the most curious and intensely interesting discovery relative to this organ is Brown-Séquard's development of a startling function appertaining to the renal capsules, and which should silence forever all attempts to "deduce the incidental differences between organic and inorganic bodies from the principles evolved from dead matter" (§ 1034, Lehmann).

The anatomical details of the nervous system, especially of the spinal cord, have been also ably investigated by Lenhossék, Van Der Kolk, Brown-Séquard, and others, and impart a great interest to the study of the organic life of animals. All this, and much more of a corresponding nature, opens very widely the wonderful mechanism of organic beings, develops more forcibly that incomprehensible variety of Omniscient Design which is apparently excluded from the mechanical constitution of inorganic bodies, and thus, and in other ways, aids in placing the chemical and physical doctrines of life and disease upon their proper

level. (See *Index*, article Design.)

Nevertheless, it must be conceded that this knowledge does not indicate the functions of organs, or their modus operandi, or the physiological laws which they obey, nor ever will. It simply enables us to trace out the channels through which the properties of life carry on their stupendous work (§ 130, 131; Bichat, Liebig, Milton). As it affects, therefore, in no other respect the facts and the doctrines set forth in this work than to give them confirmation, I shall not advert specifically to the dis-

coveries in this branch of Physiology (§ 2 c, 83, 131, 133 a, 136, 699-708).

THE NERVOUS SYSTEM. SYMPATHY.

1037, a. There is, however, one discovery relative to the nervous system, which, although it do not disturb in the least any law or proposition laid down in these Institutes, but goes to confirm the whole, and, withal, corrects a partial error in the supposed functions of a portion of the spinal cord, I shall now state in a summary manner. I need not say that this interesting disclosure comes to us from Dr. Brown-Sequard, whose genius and industry have also enlightened the physiological world upon special influences of the nervous system, which, if not as important in their relations to the laws of that system, are more attractive. Among these may be mentioned his remarkable experiment of producing epileptiform convulsions, through a special association of the nervous influence with a particular point in the skin by sections of the spinal cord, and an extension of the researches begun by Petit, Magendie, and Flourens, upon turning and rolling, developing, apparently, as in the auditory nerve, centres of nervous influence in the nerves themselves; which appeared in a collation of his writings, entitled "Experimental Researches applied to Physiology and Pathology, p. 18, 36, 80, 84, 99; 1853.

These experiments, therefore, like Bernard's, of pricking the medulla oblongata (§ 1032, d), not only possess a refreshing novelty, but constitute new and forcible methods of demonstrating the influence of the nervous power upon organic actions and muscular motion, and of illustrating the laws of sympathy; while, also, they contribute a welcome part in rescuing Physiology from Organic Chemistry (222–235, 452–

530, 635, 893 a, c, 902, 905 a, 924).

§ 1037, b. Brown-Sequard's discovery relative to the spinal cord modifies the statement made in the brief sections 465, 468, at pages 290, 291, so far as the experiments show that a division of the posterior roots of the spinal nerves does not destroy sensation, and which are conductors only to the central gray matter. It would have been sufficient, therefore, to have stated this fact (in itself unimportant to these Institutes), did not the experiments reflect, in other respects, a great amount of light upon our doctrines of remote sympathy, and place them upon a clear and intelligible ground. They present, also, an admirable analysis, as I apprehend, of the anatomical media of common and specific sensibility (§ 188 b, 197–199, 450), and that element of remote sympathy which I have designated as sympathetic sensibility, and which belongs especially to the organic life of animals (§ 197, 201–204, 451 d, 903). The conclusions at which Dr. Brown-Séquard arrived are summarily and well expressed by a Reviewer as follows:

"1. The idea that the sensitive impressions are conducted to the encephalon along the posterior columns is entirely erroneous. 2. The gray matter of the spinal cord, although itself deprived of sensibility, is an organ of transmission of the sensitive impressions. 3. There are two kinds of sensitive fibres in the posterior columns of the spinal cord, some going up towards the encephalon (centripetal or ascending fibres), some going in the opposite direction (centrifugal or descending fibres). 4. There are also ascending and descending fibres in the posterior gray horns, and very likely in the posterior parts of the lateral columns. 5. These ascending and descending fibres in the posterior columns come mostly, if

not entirely, from the posterior roots of the spinal nerves. 6. The posterior roots send also fibres to the posterior gray horns, and very likely to the posterior parts of the lateral columns. 7. All these fibres soon leave the posterior columns, the posterior gray horns, &c., in order to go into the central gray matter. 8. All these sensitive fibres decussate very near to their entrance into the spinal marrow from the posterior roots. 9. There are some transverse fibres in the spinal cord, coming from the posterior roots, which do not seem to transmit sensitive impressions. The motor nerves remain, after their entrance into the spinal marrow, on the same side, until they reach the lower part of the medulla oblongata, where they decussate."—Medico-Chirurgical Review, p. 183, July, 1856.

In his work on "Experimental Researches applied to Physiology and Pathology" (1853), after relating his experiments on the crossed transmission of impressions in the spinal cord, the Author remarks: "I believe I am entitled to conclude, from the facts above stated—1st, that most of the impressions made on one side of the body are transmitted to the sensorium by the opposite side of the spinal cord, so that the impressions on the left side of the body are transmitted by the right side of the spinal cord, and vice versa; 2d, that the assumed function of the crossing of fibres in the pons Varolii, and the neighboring parts, does not belong to these fibres, but to the fibres of the spinal cord, all along which they cross each other" (p. 67, 68).

The foregoing, and other experiments, were repeated by Dr. Brown-Séquard in some of the Medical Colleges of this country during the winter of 1856-7, at many of which the present writer was so fortunate as

to be a spectator.—Note AA p. 1131.

§ 1038. The experiments upon the auditory and other nerves (§ 1037, a), which (as well as the organization of the nerves, particularly the auditory) denote special centres of nervous influence in the nerves themselves, concur with other facts in supplying indications through which we may quite readily comprehend the philosophy of contiguous sympathy. The plexuses, also, and the ganglia, are thus rendered more palpable media through which, in part, the phenomena are brought about (§ 487 q, 497, 499 a, 516 d, No. 9, 520-523, 524 d, No. 4, 893 a, c).

THE NERVOUS POWER. ORGANIC PROPERTIES.

§ 1039. Moreover, we are indebted to Brown-Séguard for a multitude of experiments illustrative of the laws of reflex action, as applied by myself to pathology and therapeutics (see references p. 912), and variously establishing the laws of the vital functions as set forth in these Institutes (§ 462-494, &c.). The experiments enforce the distinction between the nervous power and the properties of organic life (§ 167, 168, 170 a, 172, 175 a, b, 176-178), assure us that the former acts only as a stimulus, or other modifying cause, to the organic properties, variously modifying organic actions, and developing muscular motion, voluntary or involuntary, through its operation upon the essential properties of life that are inherent in all parts, profoundly concerned, as a modifying agent, in the processes of disease (\$ 222-240), and fulfilling the great laws of sympathy (§ 452-534). Some of these results are remarkably open to observation; such as the influence of the nervous power upon the small bloodvessels, and vessels of secretion, whether by irritating or dividing a nerve. That by our Author, of paralyzing arteries by the division of nerves, confirms the similar ones by Buniva and others

(§ 399, 485), and, with analogous observations, establishes the doctrine inculcated in these Institutes upon the main ground of the phenomena of life, that the whole Capillary System possesses the power of an active dilatation and contraction (§ 384-387, 392 a, d, 393-399, 410, 411, 746, 747, 914-920, 929-934, 940, 947, 950, 951, 961, 974, 975, &c.), "My experiments prove," says Brown-Séquard, "that the bloodvessels are contractile, and that the nerves are able to put them in action."—(Exper. Res., &c., p. 10, note.) As an example, Claude Bernard produced dilatation of the bloodvessels of the face by dividing the cervical sympathetic nerve; Brown-Séquard occasioned a contraction of the same vessels by applying galvanism to that nerve, and hence regards the sympathetic as the motor nerve of the bloodvessels of the face.—Ibid. This doctrine was advanced by me in 1834, in Med. Chir. Rev.—See p. 827.

Experiments of the foregoing nature have, indeed, been multiplied by Physiologists to an incalculable extent; but perhaps no one of them has revealed the prodigious influence of the nervous power upon the capillary bloodvessels and the secreting apparatus so impressively, or made such havoc with Chemical Physiology, as Bernard's simple operation of pricking the medulla oblongata (§ 1032, d). As the whole of this ground, however, has been gone over extensively in the earlier part of this work, the present reference to the subject is to simply show that the laws and principles herein inculcated have been abundantly confirmed by subsequent researches. Indeed, all these experiments are only equivalent, as it respects the functions of life, to those which were performed by Wilson Philip, and far less with the universal reference that distinguished the corresponding labors of this Philosopher, and without his great physiological objects. But these experiments appear to have been forgotten (p. 290-321, § 462-494, and p. 107, § 224, &c.). Indeed, we see it just now announced that "all these facts [late observations, but analogous to such as abound in these Institutes] establish beyond doubt that the bloodyessels, as well as muscles of animal life, may contract by a reflex action."—(Brown-Séquard, in Boston Med. and Surg. Journ., July, 1857, p. 477.) This fact alone is evidently fatal to the catalytic and every other chemical doctrine of secretion (§ 409 hh, k, 493 cc, 893 a).*

WHERE THE NERVOUS POWER EXERTS ITS EFFECTS.

§ 1040. Let us now observe where the Nervous Power exerts its effects. Authors are in the habit of speaking of the Nervous Influence as acting upon organs as a whole, and not upon their minute structure. This is doubtless for the purpose of brevity; and, although in these Institutes the Nervous Power is generally correctly represented as exerting its ef-447, 456, 483, 487, 516 a, 896, 902, 917-924, 940, 946 b, 949, 950, 951 c, 953, 961, 971-980, 986 b, 990½, 999 c, &c., I have also frequently employed the collective method. This is calculated to defeat a right apprehension of the action and compass of that power as a vital agent. I am therefore prompted, in this reference to the subject, by the desire of turning the attention of the student to the specific fact, that he may the more readily appreciate the offices of the Nervous Power in its relation to the properties of life in their fulfilment of organic functions, or as they are essentially engaged in the voluntary and involuntary movements of the muscles of animal life.

Whenever, therefore, the Nervous Power is concerned in modifying or

^{*} Kriemer had long before shown, what Bernard has lately done, the influence of the nerves upon the blood, and applied by me to important principles (§ 485, 952, &c.).

otherwise affecting the actions of organs, its influence is exerted either upon the individual bloodvessels, or upon the minute vessels by which the secreted or excreted products are generated, or upon such other minute parts as may enter into the structure of organs—reaching, therefore, to the vasa vasorum, and as well, in all these respects, to the nervous system itself when the Nervous Power is determined upon it (\$ 230, 509, 950); or, when it excites motion in muscles it is by acting upon the individual fibres through their inherent properties.

DISTINCTION BETWEEN THE NERVOUS POWER AND THE ESSENTIAL PROP-ERTIES OF LIFE.

§ 1041. Many of Brown-Séquard's experiments, as well as Bernard's and other late observers, confirm, also, the distinction which I have endeavoured to show, extensively, between the Nervous Power and the essential Properties of Life, and that the functions, whether organic or voluntary motion, are carried on by the latter, to which the Nervous Power sustains the relation of a vital stimulus. (See Index, Articles Nervous Power, Organic Life, Vital Properties, and Organic Functions.) Some of these experiments are curious as well as ingenious. As examples:

"I have succeeded," says Brown-Séquard, "in keeping alive, from the 8th of April until the 4th of July, a young cat, about which I have already published a note in Med. Exam., 1852. The palsied parts in this animal had grown in length as much as the sound parts. The growth was such in the palsied limbs that they had acquired more than double the length they had at the time of the operation. The functions

of organic life appeared to exist without any disturbance."*

Again, says our Author:

"I lately made an experiment with a view of ascertaining how long a limb, separated from the body of an animal, may be kept alive by means of injected blood. I succeeded in retaining local life in one of the limbs of a rabbit more than 41 hours. The animal was a very vigorous, full-grown one. I killed it by hemorrhage, and, two hours afterward, rigidity had begun in most of the muscles of the two posterior limbs, and only a few bundles of muscular fibres had still a slight irritability. A fine injection of defibrinated blood was then pushed in the femoral artery of the right posterior limb. Fifteen minutes after the beginning of the injection, local life, i.e., irritability, was restored in the limb receiving blood, and cadaveric rigidity had disappeared."—Experimental Researches, &c., ut cit., p. 15, 92. Also, § 109 b, 171, 193, 261, 264, 493 cc.

Corresponding with these observations are many others in a chapter "On apparently spontaneous actions of the contractile tissues of the animal body" (ibid., p. 101-124). In speaking of Spontaneous Movements in limbs of persons who have died of Cholera, our Author remarks, that "Physicians who know how quickly after death the nervous system loses its vital powers will admit easily that these movements cannot be the result of the action of that system." Certainly not, any farther than as the Nervous Power operates as a stimulus to the organic properties, the probability of which, in the cases before us, I have endeavoured to show in § 637. In these cases the Nervous Power is maintained in operation after apparent death by the special influences of the disease. Something like this is seen in the rise of temperature in subjects dead of apoplexy (§ 447, d). And this leads me to refer to the common phraseology, "exhaustion of the nervous power," to express conditions of the system which

^{*} In such cases the palsied parts continue to be supplied with the modifying stimulus of the nervous power through the sympathetic nerve (§ 461½, 487 b, 483 c, 490).

are especially due to its powerful operation (§ 940-952). The expres-

sion is evidently without any meaning.

§ 1042. But, as I apprehend, the foregoing phenomenon, in being analogous to the movements of the limbs which take place in decapitated animals, is very different from the contraction of the intestines, the heart, &c., which take place even after the extirpation of the organs (§ 259–265); and I am happy to quote Brown-Séquard as sustaining an important doctrine in these Institutes, that, "contrary to the general opinion, a nervous action is not necessary for these contractions," but that they may be excited by other stimuli (§ 264, 475\frac{1}{2}, 476\frac{1}{2}c, 498 e).

But the special object of this section is to refer to our Author's experiments upon the iris. In 1847 he disclosed the curious fact that light may act as a direct stimulus upon this organ, "so as to produce a contraction of its muscular fibres, manifested by a constriction of the pupil." Very recently, in the London Philosophical Transactions (as quoted in the London Philosophical Magazine), he announces the results of farther experiments, which show that the pupil of an exsected eye contracts and dilates, alternately, according to the degree of light. "I uniformly found," he says, "that the yellow part of the spectrum acted as well as undecomposed light, and that the other parts had either no action at all, or only a very slight one" (§ 1881, d). "From these experiments it follows that it is not the chemical or calorific rays, but the illuminating," which produces the phenomenon; that "it is not a chemical action, but that it is by a peculiar dynamical influence that light produces contraction of the iris." "The power of the iris to contract when stimulated by light lasts extremely long, particularly in certain animals. In eels it lasts sixteen days in eyes taken out of the orbit." Muscular fibres, therefore, "may be stimulated without the intervention of nerves. In the iris of the eel the nerve-fibres are found very much altered a few days after the extirpation of the eye, and they are almost destroyed in twelve or fifteen days after extirpation, i.e., at a time when muscular irritability is sometimes still existing."—London Philosophical Magazine, Supplement, p. 520; July, 1857.

The foregoing experiments go with a multitude of others in showing that the power by which motion is carried on is implanted in all parts, and that the nervous power is simply a stimulus in developing motion, and, therefore, to a certain extent, on common ground with other stimuli (§ 205–215, 233, 259–265). But they are less remarkable in this respect than some other examples which I have quoted in the Medical and Physiological Commentaries, particularly the pulsation of an extirpated heart of a sturgeon after "the auricles had become so dry as to rustle

when they contracted and dilated" (vol. i., p. 17).*

The interesting fact relative to the iris of an extirpated eye is its obedience to light, while it is not affected by mechanical irritants. We may not conclude, however, from the experiments, that light has any direct action upon the iris in the natural state of the organ. On the contrary, I apprehend that Nature has not adopted any such multiplication of causes, but that she has placed that muscle entirely at the disposal of the nervous influence, and by which the direct action of light upon it is counteracted; nor will it be an easy matter to disprove a conclusion so well sustained by all analogy (§ 500 l, 514 k, 1072 a). Could we, however, reason in this case from analogies supplied by plants, the phenomenon would be readily intelligible. But I apprehend that it is merely an

^{*} This extreme case is related circumstantially in Dunglison's Human Physiology, vol. ii., p. 148, 1836.

incidental result of the organic constitution of the iris in its relation to light as a remote exciting cause.*

ANIMAL HEAT IN CONNECTION WITH THE NERVOUS SYSTEM.

§ 1043. Among the contributions to Physiology made by Brown-Séquard few are more interesting than those relative to the production of Animal Heat, and which concur in demonstrating (what is so extensively presented in these Institutes) its dependence upon a purely vital process, and, therefore, independence of any chemical agencies (§ 433–448). Some of these experiments I shall state briefly, and would invite the advocates of the chemical rationale to interpret the phenomena through any known analogies in the world of mere matter, if they can; or render the supposed connection between the Nervous Influence and the forces of inorganic bodies in the production of animal heat, or any other result of life, in the slightest respect intelligible. But let us hear our Author.

\$1044, a. In his experiment of dipping a hand in cold water two facts are farther confirmed through which, in part, I had endeavoured to show that animal heat does not obey the laws of dead matter, and that

its production is a vital, not a chemical phenomenon. Thus:

"I have found," says Brown-Séquard, "that the chilling of one hand plunged in water, at the temperature of freezing-point, acted very strongly on the temperature of the other hand. But, at first, there is no regularity at all in the quantity of degrees of temperature lost by the hand which remains out of the water; and, secondly, we have found once that this hand did not lose any fraction of its temperature. In one case we have observed that the hand kept in the atmosphere did lose 22° F. in seven minutes. The ordinary loss of temperature has been of between 6° to 8° F." But observe that "the greatest diminution of the temperature of the mouth has been nearly 1° F., and this only in one case."—

(Exp. Researches, &c., p. 33.)—Note T p. 1125.

Now, in the first place, is seen in the foregoing paragraph a strong exemplification of reflex nervous action in its relation to animal heat, and it is peculiarly valuable to the Vital Physiologist, since it is the same as concerns any other organic product (§ 446, a), places the whole on common ground, and as fully pronounced by Bichat, Hunter, and Philip, and as set forth at page 270, § 447, d, &c. Secondly, the experiment is not less important in showing that the cooling of the hand in the atmosphere was not at all owing to the general reduction of the heat of the body, and therefore effectually contradicts the law of slow communication of caloric which obtains with dead matter, as applied to animal heat by Edwards, Liebig, Roget, Billing, and others, who cultivate the chemical hypothesis (§ 438 a-c, 440 e). It is also an exception to our Author's doctrine that "a great many facts prove that the degree of temperature and of the sensibility of a part is in close relation with the quantity of blood circulating in that part." (Exp., &c., p. 9.) Indeed, our Author remarks, that "Dr. Tholozan and myself have observed that the greater the pain felt, the more the temperature was diminished in the hand left in the air" (p. 34).

§ 1044, b. The foregoing experiment was reversed by immersing the hand in water at a temperature of 108° F. But our Author "found no evident deviation of the temperature of remote parts, as the mouth and hand, not immersed in the water."—(*Ibid.*, p. 35.) This experiment

^{*} When Physostigma, applied on the eye after death, produces contraction of the iris, it must be through the motor ciliary nerve.—1864.

contributes with the other, by its failure of a sympathetic effect upon the opposite hand, in illustrating the effect of the nervous influence in modifying the calorific function, through the well-known fact that cold is of incomparably greater power, in this respect, than heat; while the analogy supplied by the increase of urine on the contact of cold air with the surface of the body (as related to the sympathetic reduction of temperature in the hand that was not immersed in water, § 1044, a), goes to the proof that animal heat is as much a product of vital action as any of the more sensible secretions. But all this is entirely allied to the production of pneumonia, and other inflammations, by a very temporary chilling of the surface of the body, and is mostly interesting to the Physician by its association with these greater phenomena, since it is of no little importance in practical Medicine whether a diminution of animal heat depend upon a mere chemical contingency, or some profound lesion of the organic functions (§ 1057 g).—Note AA p. 1131.

From these premises, it appears that when the temperature of the body falls from the application of cold to the surface, or rises from that of heat, the local action induced on the surface, and mostly so the reduction or elevation of its temperature, are of a vital nature, and that the general or constitutional effects are sympathetic, as set forth at p. 246, § 440, e, and shown by many direct facts, some of which may be seen

at p. 253, § 441, d.

§ 1044, c. Farther on (*ibid.*, p. 73–77), our Author has a Chapter on Experiments showing the effect of injuries of the nervous system upon animal heat, which concur with the foregoing (§ 1044, a, b) in their only intelligible import, and bear a general correspondence with those to which reference is made in these Institutes, but which are examined more particularly in the Medical and Physiological Commentaries, in the Essay on Animal Heat. But the modifications of animal heat by morbid influences upon the nervous system, of which our Author has but little to say, are far more important in a physiological, as well as practical, sense, than the experiments (§ 446–447, d).

But our Author is far from being alone in the more recent experiments which contribute with the older ones in illustrating the effects of the nervous influence upon the generation of animal heat. Bernard has been largely in this field; and Budge and others have followed up the inquiry. As all these observations, however, correspond with what had been before ascertained, and only go with the earlier to confirm the doctrine about which these Institutes have been interested, their statement

would be superfluous.

§ 1045. Séquard has, also, many observations to show the difference of temperature in different parts of the body, which correspond with those of Bichat, Hunter, Davy, and others (p. 270, § 447, d, &c.), and which I have employed as another proof that there is no analogy between the laws which regulate the temperature of warm-blooded animals and dead matter; for it had been well determined that every part has not only its own independent heat, but, when not exposed to the contact of the air, the temperature is without change in the several parts respectively, however much it may differ in any two contiguous parts (p. 270, § 447, d).

This very palpable proof has hitherto received no attention at the hands of the Chemist; but its accumulation must lead to a recognition of the fact, and not only dispose of the doctrine of free interchange of

heat as resulting from the contiguity of parts, but present an equal obstacle to the chemical hypothesis in the failure of the blood to produce an equilibrium of temperature, as would of necessity be the case were there any applicability to warm-blooded animals of the fundamental laws of an interchange of caloric which obtains in dead matter (§ 440 e, No. 14, 1034). Nor has this fact ever been stated as an objection.

FARTHER FACTS RELATIVE TO ANIMAL HEAT FROM THE ARCTIC ZONE.

§ 1046. In treating of the function of Calorification (p. 234-279) I have examined, extensively, Liebig's philosophy of Animal Heat, and I have brought up, among other objections, numerous facts which contradict the assumed ratio between the consumption of food and of oxygen gas as the main element of a uniform temperature, and the superadded contingency of clothing as one of the subordinate means; and have followed him into the Arctic regions to inquire into the accuracy of his facts. It is now my purpose to extend this inquiry by consulting the experience of a late Explorer of the North, from which it will be seen that food and clothing are even less important to animal heat than to other products of organic life. This information is obtained from Dr. Kane's late Arctic Explorations, and will be stated in a rather desultory manner. I might, indeed, appeal for similar facts to other explorers who have wintered in the Arctic Regions since this work was published; but Dr. Kane is the latest, most capable, and has supplied ample materials. I shall also dispense with farther comment, which has been fully provided in the earlier pages. But I shall do the work thoroughly in other respects, that this subject may be taken completely out of the hands of Chemistry.

It may be farther premised that Dr. Kane became ice-bound at Rensselaer Bay, in latitude 78° 58′, in September, 1853, where he remained till the spring of 1855, and that the following observations refer to that

latitude, or to his more northern winter expeditions.

§ 1047. In the first place, Dr. Kane presents a general fact which corresponds with what I have said of acclimation and constitution, in their relation to organic heat and vital habit (§ 441 b-442 c, 443 c, d, 447 g, h,

535-540, 615-619, 626 b, &c.). Thus, our Author:

"The mysterious compensations by which we adapt ourselves to climate are more striking here than in the tropics. In the Polar Zone, the assault is immediate and sudden, and, unlike the insidious fatality of hot climates, produces its results rapidly. It requires hardly a single winter to tell who may be the heat-making and acclimated man. Peterson, for instance, who had resided for two years at Upernavick (lat. 72° 40′), Another of our party, George Riley, seldom enters a room with a fire. with a vigorous constitution, established habits of free exposure, and active cheerful temperament, has so inured himself to the cold, that he sleeps on our sledge-journeys without a blanket or any other covering than his walking-suit, while the outside temperature is 30° Fahrenheit below zero (§ 440 c, No. 11, 442 a, b). The half-breeds of the coast rival the Esquimaux in their powers of endurance. The North British Sailors, of the Greenland seal and whale fisheries, I look upon as inferior to none in capacity to resist the Arctic Climate" (§ 1048, b).—KANE'S Arctic Explorations, vol. i., p. 245.

§ 1048, a. We will now come to the subject of Food, which plays so conspicuous a part in the chemical philosophy of Animal Heat (§ 440, a,

Nos. 1–8), though there will be something more about clothing (§ 440 c, 1047). I may say, however, at once, that Dr. Kane and his party were capable of maintaining their natural temperature with constitutions impaired by disease, and when often nearly destitute of food, fuel, and proper clothing, and with the thermometer ranging for months from 60° to 90° Fahrenheit below the freezing point.

Our Author intimates that he had little faith in alcohol "as a fuel for the furnace" (§ 350\frac{2}{3} f, 438 b, c, 440 bb, No. 9, 441 b, c). He had three laws, only, for the government of his party, the second of which was, "Abstinence from all spirituous liquors." This law was uniformly en-

forced, and alcohol was "burned" for cooking purposes alone.

During his long detention at Rensselaer Bay the daily journal is mostly made up of a recital of hardships, of which the privation of food, want of fuel, and destitution of clothing, form the most appalling. It is this feature of the Narrative, this incessant struggle for the maintenance of life, which forms its main interest; and the development which is thus afforded of a very extraordinary man constitutes the great merit of the work, and reconciles us to an otherwise fruitless undertaking. The fiction of "Robinson Crusoe" is no match for our Author's realities. He found, it is true, some benevolent sympathy among the Esquimaux, but encountered in the Bears a foe that was equally struggling for life. They devoured the food at the several depots, and it became often exhausted on shipboard.

Under these circumstances winter expeditions were undertaken into still more Northern regions, with the thermometer fluctuating from 40° to 60° Fahrenheit below zero—often 90° below the freezing point. In the first of these enterprises they were cheered on by the depots before them, but soon to suffer the chill of disappointment, and an unsatisfied hunger. Nor did Summer bring them relief; for, in its very midst, only the most scanty supplies of food could be obtained. On the 8th of July, 1854, our Author records in his journal that "we have neither health, fuel, nor provisions." (Vol. i., p. 312.) July 17th, 1854, he writes, "The young ice bore a man this morning. It has a bad look, this man suspecting August ice. It is horrible—yes, that is the word—to look forward to another year of disease, and darkness, to be met without fresh food and without fuel." "Moss was gathered for eking out our winter fuel; and willow stems and stone-crops, and sorrel, as antiscorbutics, collected and buried in the snow." (Vol. i., p. 343, 348.)

The party entered upon the second winter "a set of scurvy-riddled, broken-down men; our provisions sorely reduced in quantity, and altogether unsuited to our condition;" and the Engraver has added a por-

trait of the spectacle. (Vol. i., p. 349.)

October 26th, 1854, thermometer 66° Fahrenheit below freezing. January 7th, 1855, thermometer had been ranging since from 70° to 92° Fahrenheit below the freezing point. At this time he also writes, "We require meat, and can not get along without it. Our sick have finished the bear's head, and are now eating the abscessed liver of the animal, including some intestines that were not given to the dogs. We have now about three days' allowance; thin chops of raw frozen meat, not exceeding four ounces in weight for each man per diem" (§ 440 bb, No. 9). A few days later, January 30th, he says, "I gave Wilson one raw meal from the masseter muscle which adhered to another old bear's head I was keeping for a specimen." (Vol. ii., p. 17, 34.)

January 22d, Dr. Kane and Hans went on a dog-journey of 91 miles in pursuit of meat, but unsuccessfully. His outfit, in food, consisted of "a roll of frozen meat-biscuit, some frozen lady-fingers of raw hashed fox, and twenty-four pieces of ship-bread." February 4th, "I made," he says, "a dish of freshened codfish skin for Brooks and Wilson. They were hungry enough to relish it." February 9th. "Still no supplies. Three of us have been out all day (night) without getting a shot. Hans thinks he saw a couple of reindeer at a distance." "I have not permitted myself to taste more than occasionally an entrail of our last halfdozen rabbits." February 10th. "Hans comes in with three rabbits. Distribution: the blood to Oleshen and Thomas, and to the other eight of the sick more full rations, consuming a rabbit and a half" (§ 440, bb, No. 9). "My journal tells of nothing but sick men, profitless hunts, relieved now and then by the signalized incident of a rabbit killed or a deer seen, and the longed-for advent of the solar light." (Vol. ii., p. 21, 37, 41, 42, 43.)

The party lived on much in the foregoing manner till March 10th, 1855, when one of them returned from a distant Esquimaux hut with some walrus meat. Thermometer now at 72° Fahrenheit below freezing. This meat was soon exhausted. But, March 24th, there had been another windfall, of which he says, "Our ptarmigan gave the most sick a raw ration, and to-day we killed a second pair, which will serve them for to-morrow. I am the only man now who scents the fresh meat without tasting it. I actually long for it, but am obliged to give way to

the sick" (§ 440, bb, No. 9). Vol. ii., p. 83.

§ 1048, b. Again, as to the effect of cold in reducing the heat of man (\$ 1047). During the last foregoing period—March 15, "Hans and Myouk returned at eight o'clock last night without game. Their sleep in a snow-drift about twenty miles to the northward, in a temperature 54° Fahrenheit below zero (86° below freezing), was not comfortable, as might be expected. The marvel is how life sustains itself in such circumstances of cold. I have myself slept in an ordinary overcoat without discomfort, yet without fire, at a temperature of 52° Fahrenheit below zero," or 84° below freezing (\$ 440, c, No. 11). Vol. ii., p. 69.

Again: "I firmly believe," he says, "that no natural cold as yet known can arrest travel. The whole story of this winter illustrates it. I have both sledged and walked 60 and 70 miles over the roughest ice, in repeated journeys, at fifty degrees below zero; and the two parties from the south reached our Brig in the dead of winter, after being exposed to the same horrible cold."—Vol. ii., p. 78.—Also p. 257, § 442 b.

Extracts of the foregoing import may be readily multiplied. But I shall only add our Author's remark that "it is a little curious that a short allowance of food does not show itself in hunger. The first symptom is loss of power [not loss of temperature], often so imperceptibly brought on that it becomes evident only by an accident."—Vol. ii., p. 284.

§ 1049. Let us now contrast our Author's unprejudiced experience in Tea with the speculations of Chemistry upon "alcohol, blubber oil, and tallow candles," in their aspect of "fuel," as set forth in former sections (§ 440, a-bb, Nos. 7, 9, &c.).

"Under circumstances of most privation," says Dr. Kane, "I found no comforter so welcome to the party as our great restorative, Tea. We drank immoderately of it, and always with advantage." On his remark-

able retreat homewards, they "had been limited for some days to three raw eggs and two breasts of birds a day; but we had a small ration of bread-dust besides; and when we halted, as we regularly did for meals, our fuel allowed us to indulge lavishly in the great panacea of Arctic travel—Tea."—Vol. ii., p. 261, 282.

This Tea acted simply as a stimulus to the nervous system, and among its results was an elaboration of heat, just as is explained of alcohol and

animal food in § 440 b, 441 c.

§ 1050. Not a little has been assumed of the voraciousness of the Esquimaux and Samoyedes in proof of the chemical doctrine of animal heat, and there has come to be a settled belief that they would perish with cold unless forever addicted to a gluttonous repast upon walrus and blubber (§ 440, bb, No. 9, &c.). Nothing but a visit to their settlements could have deprived Chemistry of this plausible fallacy. This has been effected by Dr. Kane, who found the habits of the Esquimaux near his own winter quarters, in regard to food, precisely the same as those of other savages inhabiting tropical climates. He says of them, that

"However gluttonously they may eat, they evidently bear hunger with as little difficulty as excess," as I have endeavoured to show (§ 441, c). And again: "Among the Esquimaux generally, the coldest months of the year, January and February, are often, in fact nearly always, months of privation." (*Ibid.*, vol. i., p. 418; vol. ii., p. 131.) Near

our Author's station they were as destitute as his own party.

If we now consult the records which have been carefully made by residents in tropical regions, it will be found that where food is abundant, the savages gorge themselves far more habitually than the wanderers of the polar zone. The following example will dispose of the question before us. Thus, in the "ASIATIC RESEARCHES" there is a description of the Island of *Nicobaras*, in the Bay of Bengal (mean annual temperature 70° F.), by G. Hamilton, in which he says of its inhabitants, that

"They are very fond of sitting at table with Europeans, where they eat every thing that is set before them, and they eat most enormously. They will drink bumpers of rack as long as they can see. A great part of their time is spent in feasting and dancing. At their feasts they eat great quantities of pork, which is their favourite food. Their hogs are remarkably fat, and they eat their pork almost raw" (§ 440 bb, 441 c).—ASIATIC RESEARCHES, vol. ii., p. 382. London, 1799.—Note Oo.

"THE PRIMORDIAL CELL."

§ 1051, a. The present inquiry refers specifically to what is said at pages 36-49 (§ 63-81) on the development of the germ, and to a universal characteristic distinction between plants and animals, at § 11. The former subject possesses an importance both in a physiological and religious sense, since there are many Philosophers who assume that there is but one primordial cell which serves as a foundation for all organic beings, and that the development of this cell into a plant or an animal, or into a particular plant or a particular animal, is due entirely to the special physical influences that may act upon it, and not at all to any original difference in the structure of the cells or their endowments of life; and this assumption professes to be predicated of the revelations of the microscope; though it is not difficult to understand that the chemical doctrines of life and Lamarck's transmutation of species have had their share in the project (§ 350\frac{3}{4}-356). Upon this hypothesis, there-

fore, the only reason why men are not mushrooms is, that in one case the nucleus-cell of a human ovum is subject to physical agents, during its development, different from those which develop a mushroom. Hence it is assumed, that if it were possible to subject the germ of a plant to the agents which unfold the human ovum, it would necessarily grow into an intelligent, responsible being. This purely speculative assumption, which strikes at the whole foundation of organic nature, might be variously argued upon physiological grounds (§ 72-76, 121-123, &c.); but the necessity of this is superseded by continued observations with the microscope, which has been lately correcting its own errors (§ 83, 131), and granting us an opportunity to again believe that the Almighty created the germs of every species of animals and plants with a rudimentary structure and organic endowments as various as the species, so that each one should be developed by special physical agents alone, and the progress of development result in the particular species, and in nothing else, or, at least, in a near approximation, as in the very limited hybrid (§ 190, 1052 b).* The microscope, indeed, has ascertained that even a cell is not an indispensable requisite in the germ either of plants or of animals. To this effect I shall now quote a late able writer, who is thoroughly conversant with his subject, and without any hypothesis in view:

§ 1051, b. "The general result," he says, "of recent microscopical investigation in regard to the lowest forms of vegetable and animal life, seems to us to lead to this conclusion—that organisms may possess an independent existence, may go through all the phenomena of growth, multiplication, and reproduction, and may even possess considerable power of spontaneous motion [involuntary], without having advanced even so far in the differentiation of their powers as to possess those attributes which are involved in the ordinary idea of a 'cell' (§ 260–265). By way of explaining our meaning, we shall select an illustration from each kingdom; and the comparison of the two will enable us to inquire

in what lies the essential difference between them.

"One of the humblest known Protophytes, the Palmoglaa macrococca, whose multiplication gives origin to the green slime that is found on damp stones and walls, consists of isolated particles of a spheroidal shape and greenish color, commonly imbedded in a stratum of gelatinous matter, which an ordinary observer would at once pronounce to be vegetable cells. But a careful examination shows that there is here no definite distinction between 'cell-wall' and 'cell-contents;' the whole particle being composed of a nearly homogeneous mass of 'protoplasm,' through which chlorophyll-granules are dispersed." "These particles, increasing in size, undergo duplicative subdivision by the usual process of elongation and constriction; and it is observable that the nucleus gives indications of the commencement of this subdivision earlier than the particle which incloses it. Each new cell, if such it may be called, then begins to secrete from its surface a gelatinous envelope of its own; so that, by its intervention, the two are usually soon separated from one another." "There appears to be no definite limit to this kind of multiplication, and extensive areas may be quickly covered, in circumstances favourable to the nutrition of the plant, by the products of the duplicative subdivision of one primordial cell. This, however, is simply an act of growth precisely analogous to the multiplication of cells in the earliest embryonic condition of the higher Plants and Animals, before any differentiation of organs begins to show itself." "Now, for such a mass of protoplasm

^{*} See Notes Pr p. 1142, Qq p. 1145.

to become converted into what is generally regarded as the type of the Vegetable cell, a series of changes must take place in it, involving a differentiation between the cell-wall and the cell-contents; and this involves a greater consolidation of the external layer of the protoplasm, in a

more complete liquefaction of its internal portion" (§ 64-65).

"The successive stages of this formation may be best traced out by careful observation of the process of cell-growth in the higher Algæ; but the study of the development of new organs in Phanerogamic plants leads to the same conclusions, and the results at which Mr. Wenham has lately arrived, from observations chiefly made on the newly-imported aquatic weed, Anacharis alsinastrum, are so instructive that we shall subjoin a brief summary of them. He finds that when a new leaf is being formed from the main stem, it commences, not as is commonly supposed, in a single cell, but in the simultaneous development of some hundred at once, which make their appearance in the midst of a mass of protoplasm which is inclosed in a membrane that subsequently seems to become the epidermis of the leaf. This mass is, at first, homogeneous; but it is soon seen to contain a multitude of cavities of irregular size and shape, filled with liquid, while the protoplasm between them becomes more viscid." "These cavities are next observed to be lined with a definite membrane; and within this, protoplasm, chlorophyll, and cyclosis-currents subsequently become indistinguishable."

"Turning now to the Protozoa, we find in the Amaba, and in the Actinophrys, types of animal existence, which, in so far as we are yet acquainted with them, may be legitimately ranked on the same level as the Palmoglæa, although placed on the other side of the boundary-line. The body of each of these creatures is a minute mass of a substance which long since received from Dujardin the appropriate name of 'sarcode,' and which seems to be the equivalent of the protoplasma of the Protophyta; resembling it very closely in chemical composition and in general attributes, but being endowed in addition with a high degree of contractility. The body is not inclosed, in either of these beings, by a distinct limitary membrane, although the outer stratum of the sarcode obviously possesses more consistence than its inner part, the latter being semifluid. Vacuoles or clear spaces are seen in various parts of the sareode-body; and in these are very commonly observable alimentary particles, introduced in the way to be presently described. Besides these vacuoles, a contractile vesicle, which pulsates at tolerably regular intervals, is always to be distinguished, sometimes in the interior of the body, sometimes near its surface, and sometimes projecting above its surface."

"In these creatures, although they have neither digestive cavity, mouth, nor anus—although they are, to all appearance, nothing else than particles of animated jelly not even confined within a definite membrane, the prehension and ingestion of food, the extraction of its nutritive portion by a digestive process, and the rejection of what cannot be thus reduced

by an act of defecation, are performed as characteristically, and in reality as perfectly, as in the highest animals? (§ 14, b).* Continued in § 1052.

* Darwys's late purely speculative work On the Origin of Species (an offset of the

* Darwin's late purely speculative work On the Origin of Species (an offset of the Vestiges of the Natural History of Creation, p. 183–188), in which the Author thinks that "in a distant future light will be thrown on the origin of man"! and whose title reveals its object, may be tried, in part, by the foregoing facts, and especially by those at p. 896–905, 911, 924, 927, regardless of the sheer assumption which forms the essential basis of his work. His difficulty would be as great in assigning his "one primordial form" to any other cause than "a Creator" as all its supposed variety of developments. Every relative fact in science, of any importance, contradicts the whole of this violently revolutionary scheme. See Humbolut and Lewis in connection, p. 922, 924.—1860.

THE GREAT FUNDAMENTAL DISTINCTION BETWEEN ANIMALS AND PLANTS, OR THE BOUNDARY-LINE.

§ 1052, a (Refers to § 1051). It will now be interesting to the student of Physiology to observe the Universality of Nature's laws in any one of her great departments, in the manner in which she has established a radical distinction between the vegetable and animal kingdoms, and carried out from the lowest to the highest, in both kingdoms respectively, the fundamental plan of rendering one the Producers of organic compounds out of the elements of matter, and the other Consumers of those compounds, and how this characteristic will readily distinguish the lowest species of one kingdom from the lowest of the other (§ 13-14, 18, 173, 185, 298-303; and INDEX, article Plants). By this brief recurrence to the subject, which is made for the sake of the following quotation, which brings into view the great economy of life as manifested in the boundarylines of the Animal and Vegetable kingdoms, and which confirms the principles expressed in this work (in the references to sections just made), we shall refresh our knowledge of the wonderful elaboration of living beings, enlarge our conceptions of the peculiar properties and laws by which they are governed, obtain a renewed evidence of Creative Power, and be quickened in our adoration (§ 409, 493 a; and INDEX, articles Design and Creator).* The foregoing Writer (§ 1051) goes on as follows:

"If we now compare an Amaba or an Actinophrys, in its quiescent state, with a Palmoglaa, or an equally simple Protophyte, we can scarcely assign any structural characters by which one could be differentiated from the other. But when we look at their physiological actions, how wide is the distinction. The Protophyte, like the Phanerogamic plant, obtains the materials of its nutrition from the air and water that surround it, and possesses the marvellous power of detaching oxygen, hydrogen, carbon, and nitrogen from their previous binary combinations, and of uniting them into chlorophyll, starch, albumen, and other ternary and quaternary combinations; but the Protozoon, in common with the highest members of the Animal kingdom, is, to all appearance, destitute of any such combining power, and is consequently dependent for its support upon organic substances previously elaborated by other beings; so that it must in the end derive its sustenance, directly or indirectly, from the Vegetable kingdom" (§ 13-14, 17, 303-304). "Again, the Protophyte obtains its nutriment by the absorption of liquid and gaseous molecules which penetrate its body by simple imbibition (§ 289-295, 303 d, 303½); while the Protozoon, though destitute of any permanent mouth, stomach, intestine, or anus, extemporizes (so to speak) all these organs for itself whenever there is occasion, ingests solid particles into the interior of its body, and there subjects them to a regular digestive process."

"Thus, then, by attending to the nature of their food, the mode of its introduction, and the character of their respective movements, a line of distinction may be drawn between the Protophyte and the Protozoon, scarcely less definite than that which separates the insect from the plant whose leaves it devours, or the elephant from the tree on whose tender shoots it browses."—Medico-Chirurgical Review, p. 3-7, April, 1856; New York edition. The italics are generally mine.

And now, will Organic Chemistry pretend that there are only "incidental, casual differences between living and dead matter," and that "there is no essential difference between organic and inorganic bodies,"

^{*} That plants subsist upon elements, and animals upon organic compounds, is alone fatal to "one primordial cell" (§ 1083, 1085, Norks, Pr., page 1142, Q Q, page 1145).

and that "a Chemist, totally unacquainted with organic matter, would à priori have deduced all these incidental differences of matter from the doctrine of affinity and the science of stoichiometry evolved from dead matter"! (§ 1034, Lehmann.) Nay more; I ask the Chemist if he will even hazard an assumption as to the "incidental differences" between the fundamental law which enables the Plant to exert "the marvellous power of detaching oxygen, hydrogen, carbon, and nitrogen from their previous binary combinations, and of uniting them into chlorophyll, starch, albumen, and other ternary and quaternary combinations," and that other fundamental law which deprives the Animal "of any such combining power, but renders it dependent for its support upon organic substances previously elaborated by the Vegetable kingdom?" And, before taking leave of our able Chemist, I would respectfully ask him upon what logical ground he can reconcile the doctrine of "simple imbibition" (the "lamp-wick" doctrine, § 289, 291, 350, Nos. 21, 22×65 , 23×66 , $23\frac{1}{2} \times 67$, 68, 69, 70, 25, 26, $26\frac{1}{2}$, 27×71 , 72, 73, 74, 75, 76, 77, parallel columns) with "the marvellous power possessed by Plants of detaching oxygen, hydrogen, carbon, and nitrogen from their previous binary combinations, and of uniting them into chlorophyll, starch, albumen, and other ternary and quaternary combinations?" (§ 13-18, 37-42, 48, 53, 293-295, 303-304, 360, 409 c-411, and the next following sections, 1053, 1054.) It is fatal, also, to the doctrine of unity of cells (§ 1051, α). § 1052, b. And now a word upon the philosophy of hybrid animals.

Much has been said in these Institutes upon the mutability of the Properties of Life, both as to the transient and permanent nature of their manifestations, and much as to the influence of physical agents according to the nature of these changes. This principle, indeed, lies at the foundation of physiology, pathology, and therapeutics (§ 237–240), is deeply concerned in the temperaments, vital habit, hereditary diseases, and in

all philosophical medicine. It pervades the work before us.

When the reader shall have considered the foregoing in connection, let him refer to what is said of the permanent changes which are induced in the ovum by the male parent, and according to the peculiarities of his physical and mental constitution (§ 72–81), and also to the facts attendant on vital habit, acclimation, and the general insusceptibility to a second attack of small-pox, measles, &c. (§ 535–568, 650, 653 b-d, 654 b, 659, 661, 664–666, 670. Also Index, VITAL PROPER-

TIES).

Now, we may readily discover in the foregoing facts the philosophy which is concerned in the incapacity of hybrid animals to propagate their varieties; and it reflects no little light upon our general philosophy of life, which so readily offers an explanation. This incapacity consists in the simple element that the properties of the hybrid animal have undergone such a mutation, and in strict conformity with the foregoing analogies, that the semen has lost its impregnating virtue and the ovum its susceptibility to the action of semen. Or, if hybrids be sometimes capable of fruitful intercourse for one or two generations, it only shows a correspondence in the ultimate extinction of the procreating faculty, through repeated impressions upon the constitution, with the frequent necessity of repeated vaccinations to extinguish the susceptibility to the farther production of the disease. And so of occasional repetitions of small-pox, measles, and scarlatina, before the susceptibility disappears (§ 654 b, 664). The principle is a profound attribute of life.

From the foregoing premises it is evident that any general failure of animals to propagate with each other must be regarded as a fundamental test of species. It grows out of a law implanted in the constitution of all organic nature, and a law, as we have seen, of the most comprehensive grasp. For the same reason, therefore, we may conclude that the varieties which may arise from the intermingling of different species cannot propagate themselves beyond a few generations. All this may seem peculiarly Providential. But it denotes a far more stupendous provision, in being an integral part only of one magnificent system of Unity of Design (See references in this section as to vital habit &c.).

\$ 1052 c. It is confidently stated that about nine species of diœcious plants have been known to yield fruit where it was impossible to have had any communication with the male. We shall simply place this conclusion in the category involved in \$ 1051, a. We are not, however, disposed to question the absence of the male plant, but to assume, in that event, the certainty of at least one male blossom or one hermaphrodite having been developed on the stem of the female. That is enough. And, in this conclusion, we are warranted not only by all analogy in both organic kingdoms, but by the specific facts which often occur extensively, as in the conversion of certain varieties of the strawberry (fragaria), the "Hovey," for example, into exclusively staminate, and therefore unproductive flowers (\$ 5 $\frac{1}{4}$ b, c, 74, p. 280, \$ 449, d).

ABSORPTION AND CIRCULATION IN PLANTS.

§ 1053. Although the laws which govern absorption and circulation in Plants have been hitherto variously but incidentally considered in this work, I am disposed to introduce here some more direct observations on account of the immediate bearing of the subject upon absorption and circulation as carried on in animals, and to thus, also, extend the analogy to the philosophy of vegetable heat, indicate the harmony in the laws which govern absorption in Plants, the circulation of sap, and the secreted products of vegetable organization, and the analogy between these and the corresponding phenomena of animals (§ 293–295, 381, 445 d-q, and references in 1052 a; also § 409 hh, k, 493 ce, 893 a).

§ 1054. Absorption by the roots of Plants is considered an inadequate explanation of the circulation of Sap among those who advocate the doctrine of capillary attraction. To interpret the process, the leaf, or its equivalent, has been assumed as especially instrumental; serving either as an exhausting apparatus by evaporation, or under the designation of endosmosis, or contributing its aid by supposed chemical influences, through the operation of light, upon the ascending sap. Some one of these hypotheses is considered an indispensable auxiliary to the doctrine of capillary attraction as applicable to the circulation of sap. But, in the mean time, all the remarkable facts as to the elective power of the roots of Plants in their function of Absorption are left to be resolved by "simple imbibition" or the "lamp-wick" doctrine, as it comes to us from Liebig, Carpenter, and others (§ 289–292, 1052, and references there. Also § 350, Nos. 26, 26½, 27, 77).

An ingenious application of the Chemical philosophy has been propounded to satisfy the supposed exigencies of capillary attraction not only as it respects the ascent of sap, but as affording the true solution of the downward motion; but it touches not the elective power of the roots. This hypothesis is also thought to be a new obstacle to the doc-

trine which ascribes life to a Plant, and the dependence of its circulation and unique products upon vital actions, and notwithstanding, also, that Plants possess a far greater organizing power than animals (§ 11, 42, 217, 298, 300, 1052); have exactly the same organic functions as animals (§ 249); and generate an endless variety of precise, unique, organic compounds out of a fluid constituted of the same elements as the blood (§ 34–37, 41–48, 136). The hypothesis derives, also, no little importance from its application to the circulation of the blood, and the admission that, if it cannot be sustained in reference to Plants, it must be equally groundless in regard to Animals. The doctrine comes recommended to our attention by its distinguished Advocates.

I have already endeavoured to show the want of all foundation for the more comprehensive principle set forth by Liebig, and of which the

foregoing is a corollary, that

"The Cause of the state of Motion is to be found in a series of changes which the food undergoes in the organism, and these are the results of processes of decomposition, to which either the food itself, or the structures formed from it, or parts of organs, are subjected" (§ 350, No. 7, parallel columns).

This summary principle, in which oxygen gas figures conspicuously, is the combustive doctrine of life. The Projector held it to be applicable to every motion and to all the phenomena of living beings in health and disease (\$350, Nos. 3, 7, 9, 10, 12, 15, $17\frac{1}{2}$, 21, 73, $\$350\frac{1}{2}$), and even in death (\$350, No. 49, 383). It was laid as the foundation of Therapeutics ($\$350\frac{2}{3}$). It was also made to explain our very thoughts and passions; those being also imputed to the union of oxygen with the combustible elements of the brain (\$349 e, 1076 a), and which led us to the demonstration upon "The Soul and Instinct." It is the circumstance, also, of these fundamental doctrines being still the current Medical Philosophy that has prompted another part of the Appendix (\$433, 1034).

I cheerfully conceded that the foregoing "summary principle, were it true, would be truly beautiful." I therefore felt the importance of showing that it was not only deficient in every necessary element, but was contradicted by all the phenomena of Sympathy, and by all that is known of Pathology and Therapeutics. I am thus provided with a vast series of facts in advance, which must be taken in connection with what I am now to say of the corollary from the fundamental doctrine. This corollary consists in the application of the general doctrine, above, to the

circulation of the sap and the blood. It supposes that

The movement of the sap, upward and downward, is generated in the leaf by the action of light in promoting the decomposition of carbonic acid gas, that "marvellous power possessed by Plants" (§ 350, Nos. 68, 73, 74, 76, § 1052). The imperfect ascending fluid is thus converted in the leaf into perfect sap, and the change is supposed to institute a propelling force in the imperfect juice, by which the perfected sap is driven out of the leaf and through its downward course. The force, generated in the leaf, is also considered, from the motion which ensues in that part, as the most essential cause of the ascent of the sap, or that the fluid is thus lifted from the roots to the summit of the most lofty trees. Such, then, is the ingenious doctrine which it has been found necessary to substitute for capillary attraction in expounding the circulation of Plants; as the illustration drawn from a "lamp-wick" was found to be applicable only to the radicles in their supposed office of "simple imbibition" (§ 289–293).

This principle has the merit of appearing to be equally applicable to the circulation in animals as to that of plants (§ 350, No. 73, &c.), and it forms a remarkable instance of consistency in a somewhat comprehensive range of a purely factitious hypothesis, though it is regardless of all the overpowering facts which declare its artificial character. The pulmonary circulation is said to depend upon the union of the oxygen of the air with the carbon of the venous blood, in consequence of which this blood drives the decarbonized into the left auricle. But, in the case of the systemic or greater circulation, the order of things is reversed; for here the motion is supposed to be generated by the union of oxygen with the "structures formed out of the food." The same order of events obtains in the liver-all referable to "a series of changes which the food undergoes in the organism," &c. This is Liebig's doctrine of the circulation of the blood and sap, as expressed in the foregoing quotation, and as may be seen farther in § 350, Nos. 3, 5, 6, 8, 9, 10 15, parallel columns, and § 383. But the most curious facts about it are, as I formerly said, that it "considers the circulation of the blood due to the agencies of oxygen, and not at all to the action of the heart," and that it "is the chemical substitute for the medical aphorism, 'ubi irritatio ibi affluxus,'" and that it is made the grand basis of all Pathology and Therapeutics (§ 350, No. 10, § $350\frac{1}{2}$ – $350\frac{2}{3}$). The latter, indeed, should naturally flow from the main physiological doctrine, if Nature be truly represented by this (§ 1 a, 2 b, 383, 447 $\frac{1}{2}$ a, 638, 1089).

Doubtless, this remarkable doctrine of the circulation of the blood might have been left to itself had it not been incorporated in the leading works upon Physiology, as in Dr. Carpenter's, and even carried into popular systems, as by Mrs. Willard, whose appropriation of the philosophy is regarded by Dr. Cartwright (in Boston Medical and Surgical

Journal) as singularly ingenious and original (§ 349 d, 433).

It is simply my remaining object, however, to inquire into the supposed condition of the circulation in plants, as in all other relative topics concerning man and animals the ground has been sufficiently explored, and since, also, if the hypothesis can be contradicted here, it must equally fail, as is admitted, in respect to animals. I shall also endeavour to avoid a repetition of whatever I may have hitherto said, and limit

myself to the statement of a few simple facts.

In the first place, then, it appears to me that the hypothesis contains a fatal element—the prodigious amount of force which is said to be generated in the leaf, as well as in the lungs and other soft structures of animals. On this point I am bound to abide by the decision of the Chemists, who say that such must be the consequence of the chemical changes which are supposed to be in progress for the production of motion. As expressed by these Philosophers, who designate it as "an inexpressible force," or compare it, like Liebig, to a "steam-engine" (§ 350, No. 15), it would be abundantly sufficient for any purposes in artillery or in blasting rocks (§ 392, c).

In the next place, there are many other circumstances attending the circulation in Plants, as well as Animals, not hitherto considered, which it would not be easy to interpret by the Chemical doctrine, but which are readily explained by the Vital. Where, for example, is the auxiliary power to capillary attraction (if the latter be included)—where, the leaves, or even buds, when vegetation starts from its hybernating state in northern countries? Observe the Acer saccharinum—the remarkable

vigour of its circulation before there is a development of the bud. Indeed, the harvest of maple-sugar often takes place in the Northern States while the earth is covered with snow to the depth of many feet. The circulation, too, is most vigorous after frosty nights succeeded by warm mornings; and when the temperature of the air rises, for a night or two, to some 40° F., the flow of sap is apt to be greatly diminished, but is restored in profusion on the return of frost. What in Chemistry will explain such a phenomenon? And, if it retreat before obstacles of this nature, must it not abandon the whole ground? Nay, how palpable the force of a single fact, when it is considered that the phenomenon is due to the effect of heat as a vital agent on the irritability of vegetable organization, and, singularly enough, as admitted by Liebig (§ 350, No. 65); and whether operating at the higher and more uniform degrees, or alternating at the freezing point, the exact explanation is involved in the law of Vital Habit, as set forth in these Institutes at pages 363-370.

Such, mainly, is also true of the Vitis vinifera, which was the subject of many ingenious experiments by the celebrated Dr. Hales, as appeared in his Vegetable Statics. And this brings us upon the fashionable ground at which I have been aiming—that of "Experimental Philosophy." These experiments are allowed to have been ably and critically conducted, and are standard references. Let us, therefore, interrogate some of these experiments, and see how far they correspond with Nature, or how far they contradict her and bear out the Chemist; and let us, at the same time, take along the corroborating testimony of other eminent observers, who were obliged to conclude that "the sap moves with such velocity and force, that it must be propelled by vital contractions and dilatations of the vessels" (§ 293). Now, in some of Dr. Hale's experiments there was not only an absence of leaves and buds, but the stump alone was the subject of observation. There was wanting, therefore, every thing that could contribute to the fundamental requisite of the Chemist, and, indeed, I may say, what is considered indispensable by all the physical Philosophers to the simple doctrine of capillary attraction as it regards the ascent of sap. Take, as an example, Exp. xxxvi. Thus:

"April 6th, at 9 A.M. I cut off a vine, on a Southern aspect, two feet nine inches from the ground. The remaining stem had no lateral branches. It was seven eighths of an inch in diameter. I fixed on its top the mercurial gauge;" of double curve, to admit the flow of a few inches of sap.

For several days the mercury was more or less pushed up by the sap, according to the state of the weather. "April 14th, at 7 A.M. the mercury rose to 20 inches high. At 9 A.M. 22 inches. Fine warm sunshine. Here we see that the warm morning gives a fresh vigor to the sap." "April 18th (12th day), at 7 A.M. mercury 32 inches high, and would have risen higher if there had been more mercury in the gauge. From this time to May 5th the force gradually decreased [the life of the plant giving way]. On the 18th of April the force of the sap was equal to 36 feet height of water. Here, the force of the rising sap in the morning," the doctor concludes, "is plainly owing to the energy of the root and stem."

In another and similar experiment, at the same time, "the mercurial gauge being fixed near the bottom of a vine, the mercury was raised by the force of the sap 38 inches, equal to 43 feet +3 inches $+\frac{1}{3}$ height of

water; which force is near five times greater than the force of the blood in the great crural artery of a horse; seven times greater than the force of the blood in the like artery of a dog; and eight times greater than the blood's force in the same artery of a fallow doe," as ascertained by

the rise of the blood in long glass tubes.

In these experiments it is sufficiently manifest that all the physical hypotheses fail, since all of them assume that the leaf, or its equivalent, is indispensable to the progressive rise of the sap. The result, I say, shows, what all organic nature teaches, that so important a function as the circulation, and so exceedingly variable as in plants, yet most exactly suited in every species and every individual (but varied in all the species), to the methodical steps in vegetation, is not dependent upon the capricious operation of any chemical or physical agencies, and that a force is established at the very base of a plant, that shall not fail of the exigencies of vegetable life according to its progressive changes (§ 392 b, 394); and the same general principle may be affirmed of every great function of organic life. It follows, therefore, that the sap is moved by something peculiar to living beings, and this is called a vital The motion which we have seen, however, would prove utterly destructive to the leaf, and even to all delicate branches, without a gradually countervailing influence upon that action, and the subdivision of vessels will not alone explain the diminution of force. We must hence infer, what is denoted by other important facts, that the reduction of force arises, also, from a modified action in the vessels leading to the twigs and bud, as well as in the bud, or leaf, itself. Here a new action is set up, and a new motion of the sap begins, which is propagated along its downward course by a universal action of the vascular system, modified in different parts according to the special final causes of each part.

Although there were no leaves in the foregoing experiments, and, indeed, only a short stump of the vine, the results were not unexpected to the Philosopher, who adopts the theory that the circulation of sap is owing to temperature. But temperature could not be always made to explain the phenomena, Capillary Attraction was little understood, and Chemistry was yet unfledged. Accordingly, as in all cases where genius departs from Nature, even the acute mind of Dr. Hales has a special hypothesis for each apparent difficulty; sometimes borrowing from the theory of the Vitalist, though less so than most Organic Chemists, and, like the latter, actually raising hypotheses in direct opposition to each other (§ 350, &c.). Take the following examples, where the leaves had obtained their full development, and which will farther show the error

of the physical hypotheses. Thus:

"July 4th, at noon, I cut off within three inches of the ground another vine on the South aspect, and fixed to it a tube seven feet high, and filled it with water, which was imbibed by the root, the first day, at the rate of a foot in an hour, but the next day much more slowly; yet it was continually sinking, so that at noonday I could not see it so

much as stationary"—the life of the stump now giving way.

Here are two important facts. There was no apparent upward force, though there may have been some mingling of the sap with the water; and, secondly, the water being vitally adapted to the plant, it was literally carried down to the roots from the tube at the rate of a foot an hour. There was no chemistry here to effect or in any manner influence the descent; and the water went the wrong way for capillary attrac-

tion. The hypothesis of gravity would be absurd, while it is, also, contradicted by the preceding experiments; and the descent of the sap has been a greater problem to our rival friends than its ascent. The importance and compass of the proof will be at once perceived. But he, who made the experiment, seeing the want of agreement with the preceding, thought, like a great many other Philosophers, that a conflicting fact would justify a special hypothesis. Let us therefore hear the doctor upon this troublesome point. Thus:

"Now, since the flow of sap ceased at once, as soon as the vine was cut off the stem, the principal cause of its rise must, at the same time,

be taken away, viz., the great perspiration of the leaves."

That is the doctrine, along with capillary attraction, of a large section of the physical school; but it supplies no aliment to Chemistry. In all the cases, the blunders arise from a defective observation of facts, and from an ignorance in the difference between the physiological condition of the vine and of other plants before and after leafing (§ 1034). In the experiments first recited, the vine was in its budding season, when vegetable life is in highest activity, and hence the profusion of sap, the force of its circulation, and the development of heat (§ 445, e, f). On the contrary, in the last experiment Nature had accomplished her greatest of objects in the development of the leaves; and Dr. Hales might have amputated the largest limb, with all the other leaves remaining, and there would have been no bleeding. The same descent of the sap would have occurred, and prompted a different hypothesis.

And now contrast the foregoing experiment with his conclusion as expressed in *Exp.* xxxviii.; the words in *italics* being designed by myself to facilitate the hasty reader. It is a hypothesis, directly opposed to the

preceding, for the purpose of expounding another fact:

"The sap," says the doctor, "begins to rise sooner in the morning in cool weather than after hot days; the reason of which may be, because in hot weather much being evaporated, it is not so soon supplied by the roots as in cool weather, when less is evaporated." In Exp. xlvi. he says, "It was found that the trunk and branches of vines were always in an imbibing state, caused by the great perspiration of the leaves, except in the bleeding season," when there are no leaves. At that season the problem of the stump led him to conclude that "the force of the rising sap is plainly owing to the energy of the root and stem" (Exp. xxvi.). Will the

Chemist explain?

In one of his experiments he attributes an effect to the "sun's warmth," in making the vessels "dilate and contract a little." This is what he means by "the energy of the root and stem." Had he adhered to that explanation, and had he a competent knowledge of the physiological laws of vegetable life, he would have had no difficult problems to expound, no conflicting experiments, no contradictions of himself. Few Philosophers, however, as little informed in the philosophy of organic life, have been as accurate in their experiments, or more capable of reasoning upon the facts, than Dr. Hales. But thus it ever is with all who depart from their main field of operations to build up the difficult parts of other sciences. Hales was a divine, and, although adroit in experiments, and better qualified by impartial habits than the Chemist, it is no detraction from his (or their) exalted merits to say, that he knew so little of Physiology he was incapable of applying or even perceiving the facts which the student of organic nature may readily seize and convert to the phi-

losophy of life, and turn against the conclusions of the original ob-

server (p. 923-925, Humboldt).

Am I not, therefore, entitled to conclude, from these few observations alone, that organic beings are contradistinguished from inorganic by what is popularly known as life, or vitality, and with the summary remarks of one of the greatest scientific Botanists of the age, Professor Lindley, of the London University, as expressed in his able analysis of the "First Principles of Botany," that,

1st. "The movement of the sap depends upon a vital irritability, and

is independent of mechanical causes" (§ 185, 188, 188 $\frac{1}{2}$).

2d. "The proximate principles are formed by the vital powers of the plant acting, in conjunction with air and light, upon the fluids contained in its system."

3d. "All the phenomena connected with the growth of plants are caused

by an inherent VITAL ACTION" (§ 293).

§ 1055. I shall conclude the foregoing subject relative to the circulation in Plants (§ 1054) by a quotation from Liebig's "Researches on the Chemistry of Food, and the Motion of the Juices in the Animal Body," as a farther justification of what I have said of the tampering of Chemists with the philosophy of organic life, in former sections (§ 5, 276½, 676 b, 1006 a, 1034, &c.), and that it may be compared with § 350, parallel columns, and § 350½ n. It will be seen that it is nearly the common doctrine relative to the evaporation by leaves in explaining the circulation of sap, as propounded by Dr. Hales (§ 1054). Professor Liebig infers the principle from experiments made upon dried membranes! as he had formerly done of the circulation in Plants from the action of "a lamp-wick" (§ 289). Having found the membranes pervious to water, oil, &c., he proceeds to say, in a letter to Professor Horsford, republished in the "American Journal of Science and Arts" (May, 1848, p. 415), and which I quote for the brevity of the conclusion, that

"The employment of these results upon the processes in the animal

body scarcely requires a more detailed explanation.

"The surface of the body is the membrane from which evaporation goes constantly forward. In consequence of this evaporation, all the fluids of the body, in obedience to atmospheric pressure, experience motion in the direction towards the evaporating surface. This is obviously the chief cause of the passage of the nutritious fluids through the walls of the bloodvessels, and the cause of their distribution through the body. We know now what important function the skin fulfils through evaporation"! (§ $350\frac{1}{2}$, n-q.) Our Author did not even think so far as to consider the perpetual vicissitudes of the skin in that respect, nor how wonderfully the blood becomes concentrated in the great internal vessels in the sweating stage of the malignant cholera, or as the same phenomena distinguish a paroxysm of fear. It is also worthy of remark that this distinguished Leader in Physiology here loses sight completely of his universal chemical doctrine of motion, which had been put forth in his "Animal Chemistry" (§ 1054). It forms, therefore, another antagonism for the Parallel Columns.

If we may have sometimes appeared deficient in dignified sobriety on similar occasions, we have not thought it necessary to render an apology, but have relied implicitly upon the sympathy of intelligent readers; and while we have not laughed at the able Chemists who have taken upon themselves the labour of persuading Physicians that animals are only minerals, but rather at the latter, nor have been offended at the arrogance which admits no penetration of the most hidden recesses of Nature but through that veil of ignorance which betrayed the Crispin into the immortal rebuke of Apelles, we have, nevertheless, in our zeal to save something from the wreck, endeavoured to show that all the precepts of the Laboratory justify our application of that rebuke; nor do we feel responsible for any risible consequences.

EXPERIMENTS BY MYSELF TO ASCERTAIN WHETHER THE QUANTITY OF BLOOD CIRCULATING IN THE BRAIN MAY BE REDUCED ARTIFICIALLY.

§ 1056. As the question whether the bloodvessels of the brain may be brought under the influence of bloodletting like those in other parts of the body is intimately connected with the philosophy of the operation of loss of blood, as set forth in these Institutes (§ 941, 950, 975, &c.), and has an important bearing upon the treatment of inflammatory and congestive affections of the brain (§ 971-980, &c.), I shall now introduce some experiments which I made many years ago in reference to the subject before us. Whatever may be thought of the theoretical conclusions, the experiments demonstrate that the brain is on common ground with all other organs as it respects the "influences of bloodletting," and that is the important end at which I am now inviting the attention of the reader; nor am I aware that the experiments have been invalidated. They were communicated to Dr. James Johnson, Editor of the Medico-Chirurgical Review, London, in 1834, who published an abstract of the Article in the April Number of the Review for that year, and which was introduced by the following prefatory remarks:

"The Editor having received a long paper from Dr. Paine, of New York, is unable to insert it in the Med. Chir. Review, into which no original articles can be admitted, excepting some short cases or pieces of intelligence. The Editor, however, has had a short analysis of Dr. Paine's paper drawn up, &c.

J. J."

The following is an abstract of "the analysis:"

"Marked and conflicting differences of opinion prevail, relative to the proximate cause of cerebral affections. These differences we may truly ascribe to the widely opposite conclusions which Physiologists have arrived at as to the functions of the brain, more particularly of the state of its circulation. Dr. Paine instituted a suite of experiments to determine, if possible, the normal state of the brain, so far as information so

derived might be connected with its abnormal changes.

"That the brain is naturally incompressible, he regards as an established truth. But, with reference to the opinion that the cranium must always be filled, he thinks 'the spaces which exist between the parietes of the ventricles, between the membranes, the skull, the convolutions of the brain, &c., are not necessarily occupied by a serous fluid, but must be, in part, pervaded by an aqueous vapour, which is, of course, susceptible of condensation, not only from the decline of caloric, but by any power exceeding its force of expansion. And so, on the other hand, the elasticity of the vapour will promote a reduction, by loss of blood, of the contents of the cerebral bloodvessels to any extent. The existence of such an elastic vapour is inferable from what is known to exist in other cavities of the body, and from what is respired from the lungs. It must, therefore, be far more strongly pronounced in the cavity of the

cranium in consequence of the exclusion of atmospheric pressure, excepting so far as this operates through the openings in the skull.'

"To get rid of sources of ambiguity, connected with the otherwise undetermined question, whether such vapor existed naturally, or was produced during changes in the condition of the brain, experiments were performed (on calves), so as to exhaust the system of its blood. With the results of Kellie's experiments Dr. Paine premises a statement of his unacquaintance, but hazards a supposition that the animals may have been so bled by Kellie as to occasion fatal syncope 'before the body was deprived of the circulating fluid; and that, as condensation of the vapour has taken place after the death of the animal, the blood has rushed into the brain to supply the vacuum. Such, indeed, would be a necessary consequence of vapour so condensed, and of any blood remaining in the aorta, the cava, or the great branches connected with those of the head. For this reason we shall always find the cavity of the skull, in the human subject, fully occupied by solid and fluid matter, to whatever extent depletion may have been carried, unless the patient may have been trepanned during life, or before any reduction of the natural temperature. It does not, therefore, follow that vapour cannot have existed within the cavity of the skull during life because it is fully occupied by incompressible matter after death.'

"The calves were experimented upon in this way: The aorta near the heart, or the descending cava, was opened, when so rapid was the hemorrhage that the heart's action ended only on the vessels' being fully emptied. Lest condensation of vapour should possibly have arisen from reduction of temperature, the head was instantly removed after the animal died. On examination, Dr. Paine 'uniformly found the vessels of the brain and of the membranes nearly deprived of their contents, and the organ perfectly blanched.' No disproportion in the quantity of the blood was observed, whether the animal had been trepanned, or the external air excluded. The serum exhibited only 'a tinge of red' when the brain was opened up, and, therefore, there could be but very little blood in its vessels, or those of the pia mater. Not more than half a drachm, and 'always quite as much when the animal had been trepanned,' was observed in the sinuses of the dura mater. Calves were judiciously selected in preference to dogs, being less troublesome, and probably less liable to cerebral excitement during 'an operation requiring some dissection.'

"The cranial contents were determined by comparing their weight with a bulk of distilled water equal to the capacity of the cavity. The dura mater was not included, and its sinuses were not disturbed so as to admit of the entrance of water. Here are the results:

		drs.	grs.
1. Brain—skull trepanned		4	20
Water—distilled		4	10
2. Brain—skull trepanned	9	4	25
Water—distilled	9	2	0
3. Brain—skull trepanned	10	3	26
Water—distilled	10	2	6
1. Brain—skull entire	11	1	5
Water—distilled	10	7	20
2. Brain—skull entire	10	6	10
Water-distilled	10	4	50
3. Brain—skull entire	10	2	40
Water-distilled	10	0	52

"On injecting quicksilver into the human brain an equal bulk of bloody serum was always expelled. The average quantity of quicksil-

ver, on injection into the brains of animals bled to death, was 'two pounds in brains weighing ten ounces' (3x); the sinuses of the dura mater admitted the maximum of this proportion.

"If these experiments be correct, and otherwise trustworthy, less blood circulates within the head than has been supposed; and the amount of sanguineous effusion has probably been overrated, unless the ratio be

higher in the human species.

"Independently of the experiments, Dr. Paine thinks that we are authorized in believing the circulation within the substance of the brain to be slow, and the quantity of blood small. As the organ chiefly fills the cavity, little space only can be allotted to the membranes, and still less to their chief vessels. The experiments sustain the conclusions derived from anatomical facts, that the quantity of blood is much more reduced than has often been conjectured. The very sparing provision of absorbents with which the brain is provided is 'a negative argument,' in Dr. Paine's opinion, 'that the brain has less use for blood than other parts of the system, where these vessels abound.' 'To obtain a slow circulation, an abundant and equable supply of blood was required; we find this provision made. Are not those vessels large and powerful, which convey blood from the aorta to the confines of the brain? And do we not see the brain carefully protected against the force of its own circulation?' Here we cannot but admire the philosophic views entertained by Dr. Paine, which, however, the necessary limits allotted to his Article only permit us thus to glance at.—Note O p. 1121.

"The rate at which the blood circulates in the membranes is inferred to be much more active than that within the proper substance of the organ; the bulk of transmitted blood being confined to the membranes. Yet, from the tortuous course of their vessels, the circulating fluid must pass slowly compared to its progress in other great organs. It is probable, too, from such considerations, that in health the proportion of serum varies. If so, a variable state within the cranium is denoted; and the normal proportion of blood being ever, probably, nearly the same, it follows, in Dr. Paine's opinion, that 'any preternatural space must have been occupied by vapour.' In accordance with the results of our Author's experiments, we have these principles deduced for practical guid-

"'Blood may be abstracted from the brain in the same manner and

to the same extent as from other organs.

"'That there takes place necessarily an active contraction of the bloodvessels of the brain, as the exhaustion of their blood follows equally when the external air is not admitted within the cavity of the cranium.

"'That there must be a production or expansion of aqueous vapour corresponding in bulk and elasticity with the diminished quantity of blood and the decrease of pressure from the force of the heart and blood-

vessels.

"'That the natural proportion of blood found in the brain, after its copious abstraction from the system, arises from a quantity still remaining in the vessels connected with those of the head, and which rushes into the brain after death to supply the vacuum produced by the condensation of the vapour generated during the contraction of the cerebral

"Dr. Paine argues that the living system is under the government of uniform laws. Universal contraction of the bloodvessels-a contraction greater in the extreme vessels than what is explicable by the mere loss, is observed to be attendant on the abstraction of blood (§ 746 a, 912, 931, 935 b-e, 938 b, 944 a-c, &c.). Is not a similar contraction extended to the vessels of the brain, not less from the withdrawal of blood, than likewise 'through the influence of sympathy with the vascular action throughout the body, an influence rendered still more probable by the propagation of the sympathetic nerve along the arteries of the brain; that the topical abstraction of blood by cupping and leeching, if not also vesication, operates by producing a sympathetic contraction of the vessels within the brain; that inflammation of the brain is relieved on a common principle; and that opposite inferences would involve the remarkable exemption of a part from the operation of general laws, and a violation of the usual simplicity of Design?' (§ 516 d, 756 b, 893 a-i,

915-921, 939, 974, 1039).—Note Q p. 1122.

"The varying changes in the circulation of the brain renders probable the existence of an elastic vapor. This, it is inferred, is rendered yet more probable from the rapid production of vapor when the temperature is at 98° F., atmospheric pressure being removed, which must be greatly the case within the cranium, and allowing, also, for 'the resistance of the circulating fluid.' 'Equal increments of temperature, by increasing in geometric progression the force of vapor, would tend to embarrass the functions of the brain. But an admirable provision of Nature guards against the occurrence of such casualties.' As the bony inclosure excludes the influence of atmospheric pressure, minus the openings at the base of the skull, 'the generation of an elastic vapor is provided, the pressure of which at 98° F. to the ratio of steam at 212°, is as 13 to 30. It will therefore admit of an easy condensation, such probably as would be produced by an increased determination of blood to the head, and more especially by blood extravasated;* and however the general force of the circulation may be undetermined, it is abundantly obvious, from the tortuous course of the vessels, and their minute subdivision before entering the substance of the brain, that the current is here sluggish and easily resisted, even if it be admitted that capillary circulation depends upon the vis a tergo, as it does not (§ 392, c). It will not, therefore, be difficult to imagine that there exists this farther harmonious relation, by which the ordinary force of the circulating fluid is accurately counterbalanced by an aqueous vapour.'

"The minute subdivision of vessels before entering the substance of the brain—the obstacles checking the impetus of blood from the heart's action—the absence of valves in the cerebral veins—the remarkable distribution of the sympathetic nerve, &c., are, in Dr. Paine's opinion, so many powerful motives for believing that the circulation in the brain is especially dependent on a specific action of the vessels themselves (§ 392 c, &c.). The experiments tend to show that, if vapor exist naturally, its quantity must be small. A small quantity, however, is quite sufficient for meeting the exigencies of its purpose. The vapor may yet be found, it is supposed, by subsequent inquirers, to enact a most influential part in the cerebral economy, its great compressibility admitting of rapid changes in the quantity of circulating fluid; and by which, 'in severe congestions, mechanical pressure is partly obviated, and the circulation less

embarrassed in portions of the organ not involved in disease.'

"If the production of vapor under the most probable circumstances could be established, 'the uniformity of Nature, upon the questions be-

^{*} In no other way can the largest quantities of extravasated blood be explained.

fore us, would be recognized. No longer would there exist any necessity of forming new doctrines to explain analogous changes which have acquired the force of established laws among other organs; the treatment of cerebral congestion or inflammation will be again placed on the broad principle which determines the treatment of similar affections in every part of the body; and when the organ becomes the subject of venous plethora or of high vascular action—when the carotids are beating with a violence that communicates motion to the head, while the pulse in the extremities is low, feeble, and oppressed; when also the skin is cold, and the blood, which may not be determined to the head, is accumulated about the abdominal viscera, and the heart pulsates with exhausted efforts, we shall be no longer obliged to adopt the difficult rationale, that the abstraction of blood diminishes the violence of action in the brain by its impression on the vis a tergo. We shall see it exerting its influence on the vessels within the brain, as it obviously does on those of the abdominal viscera which may be simultaneously affected by congestion; we shall not doubt that it equally induces a change of action in the vessels attended by their contraction, in all the organs that may be involved in analogous affections; and we shall the more readily assent to this proposition and abandon the notion of a diminished vis a tergo, when we find, as these changes progress, the pulse rises in strength and fulness, and the heart beats with more than natural energy; which now, indeed, may require the farther abstraction of blood to lessen its violence and remove the evil it originally produced; now, indeed, the vis a tergo may become a motive for continued depletion' (§ 498 f, 750 a, 801, 806, 811-813, 961 e, 965 b, 968, 969 c, 990 i).

"From a lengthened paragraph of highly ingenious reasoning, Dr. Paine draws a corollary—that the force of the momentum of the circulation within the brain may be determined 'with an approach to accuracy,' and that its force must be 'nearly in the ratio of the expansion of vapor at 98° Fahrenheit, removed from atmospheric pressure.'"

Although the writer of the abstract is pleased to say that "with one other extract we must reluctantly conclude this notice," I shall not repeat it here, and have omitted other parts, as not being immediately rel-

ative to my present objects.

But I will add, in conclusion, that Donder has seen the arteries of the pia mater contract when the cervical sympathetic nerve is irritated. The brain was, of course, exposed; but if contraction take place under such circumstances, it is a law which must operate in the natural condition.—Donder's *Physiologie des Menschen*, p. 138, 140.

SEDATIVES.

§ 1057, a. It will be seen in these Institutes, that, immediately following the general subject of Therapeutics, and preceding that of the Modus Operandi of Remedies, and extending from page 563 to 660, are disquisitions upon the uses of various groups of the Articles of the Materia Medica, and that among the number are Narcotics, which are considered, in part, in their aspect as Sedatives. It is now my purpose to make some general comments upon the virtues, and mode of operating, of the entire group of Sedatives, and upon the differences which prevail among the several members of the group (See, particularly, p. 583–593).

I understand by Schatives those remedies whose general tendency is to diminish vascular action in a direct manner; though in some instances

they may at first produce more or less excitement, which is followed by diminished action as an ultimate result of the remedy (§ 891, q). Nay more, the excessive application of the most powerful Sedatives—loss of blood, narcotics, hydrocyanic acid, and cold, may light up inflammation or venous congestion in the brain, whilst they simultaneously exert their general sedative effects upon the system at large until the cerebral affection gives rise to constitutional excitement (§ 743, 817, 827 d, 950, 974 b, 1024). The various aspects of the modus operandi may be seen in § 891 $\frac{1}{2}$ k.

These opposite effects, however, are not common, nor is the excitement ever strongly pronounced unless the sedative proves morbific. In the extensive class of Stimulants and Tonics we are presented with agents which illustrate, by their opposite virtues, the common attributes of the Sedatives; since it is the direct and equally uniform tendency of the former to increase vascular action in a direct manner. As examples of the two Classes, bloodletting, antimonials, hydrocyanic acid, and cold, may be reckoned as standards of comparison for Sedatives, and alcoholic liquors, spices, mints, the vegetable and mineral tonics, animal food, and dry heat, as representing the virtues of Stimulants.

There are many things, however, which may increase vascular action, and induce inflammation, which operate in virtue of some irritation they exert (such as aloes, scammony, &c.), but whose action is very different from that of stimulants. Indeed, the most powerful Sedatives, as we have seen, may become irritants in excessive amount, and excite inflammation. But they can never act as Stimulants in the proper acceptation of this class of agents, but in virtue of morbific influences of an irritating nature. Irritants produce disease when Tonics will not (§ 188–191).

It appears, therefore, that Sedatives are liable to the same qualifications as we have seen of the groups of other remedies, being liable to be more or less otherwise unless rightly administered. This qualification is more strongly manifested in morbid than in healthy states of the body. There must be a pathological condition which shall be in relation to the peculiar virtues which are denominated sedative, or no sedative effect may arise from the action of the remedy, and even an opposite result may be the consequence, as often witnessed of opium when administered in high states of arterial excitement. And I am now led to remark that the term Sedative, like many other denominations of remedies, is very far from conveying an adequate apprehension of the effects produced; for the agents so called not only reduce the properties of life, and lessen vascular action, but they exert more or less of a direct alterative effect. That effect is most distinctly marked when they aggravate or produce disease. (See Index, Article Alteratives.)

§ 1057, b. Again: various Sedatives will be far from being suited to many conditions of disease, when others of the group may be in the highest degree salutary. Take two of the most powerful. Loss of blood, for example, will often save life where opium would be destructive; and, vice versa, opium will relieve the subject of gastric spasm induced by drinking cold water, when loss of blood might destroy him. Even in some conditions of inflammation, remedies which are commonly stimulating and tonic will prove sedative when bloodletting may be at least useless. Such is the case in intermittent inflammation, after suitable depletion; since Cinchona may then succeed, when loss of blood, antimonials, &c., have ceased to be curative (§ 662 b, 675, 892 m-p). This consideration brings up the importance of looking well at the patholog-

ical distinctions among closely-allied diseases, inasmuch as Cinchona. and many other agents of active tonic virtues, are directly sedative (by their alterative action), in suitable states of the system, in intermittent fever, while they aggravate all other fevers at the same early stages; and it is only the intermittent form of inflammation, and those venous congestions which have peculiar miasmata for their predisposing causes, in which Cinchona would not also prove stimulating. So far, therefore, the foregoing tonics belong to the group of Sedatives; and they show us the difficulties of artificial arrangements of the Materia Medica. These arise mostly from the compound virtues of remedies, and often, as in the case before us, from certain important virtues being developed only by special pathological conditions; for, it is not the tonic, but the febrifuge virtue of Cinchona, and analogous remedies, which does the service in intermittents. The latter is then so completely in relation to the special modifications of disease that it transcends or counteracts the morbific action of the former (§ 150-151, and references there).

§ 1057, c. In my "Therapeutical Arrangement of the Materia Medica" I have given a rather different import to the group of Sedatives than is common, having placed them as a special order of Antiphlogistics. The group is composed of such as are most capable of subduing general arterial excitement in a direct manner, though some of them may be little suited to the relief of local excitement. Thus, the narcotics, when justly applied, reduce the irritability of the whole system, and moderate general excitement. But they have no great tendency to assuage local inflammations, but, on the contrary, their tendency is more frequently to increase them. In the arrangement, therefore, of the Sedatives according to the restricted sense in which I have employed the term, I have estimated their therapeutical value according to their greatest usefulness in allaying morbid irritability and sensibility, particularly the former,

in their appropriate relations to certain conditions of disease.

§ 1057, d. We may next proceed to regard Sedatives under five subdivisions, namely, Sedatives proper; Narcotics; Cold; Alteratives capable

of nauseating, but without producing that effect; and Nauseants.

The first subdivision, or Sedatives proper, comprises Loss of Blood, Hydrocyanic Acid, Cyanide of Potassium, Cyanide of Zinc, Ferro-cyanide of Potassium, Cherry Laurel, Bitter Almonds, Hydrosulphate of Ammonia, Foxglove, Tobacco, Indian Tobacco.

The second subdivision, or *Narcotics*, embraces Opium, and its preparations as arranged in the order of their therapeutical value, Henbane, Poison Hemlock, Lupuline, Lactucarium. Add also the "Senso-Paralysants"—Belladonna, Aconite, Stramonium, and Delphinium.*

The third subdivision consists of Cold only, and in its local action. The fourth subdivision consists of Tartarized Antimony, to which Ip-

ecacuanha might be added.

The fifth subdivision, or the Nauseants, refers to such agents as are sedative only when they produce nausea. There are many of this denomination, but none of them are of much use in medicine as nauseants; but, on the contrary, they are apt to produce an injurious irritation of the gastro-intestinal mucous membrane when carried to the extent of nausea. They are, therefore, not specified in our group of Sedatives.

§ 1057, e. Now, there are certain well-marked analogies among all the foregoing subdivisions, yet each differs from the others in some very prominent characteristics. Indeed, there are no two of the remedies,

however allied as Sedatives, which do not present some strong peculiari-Take, for example, the first two of the first subdivision—loss of blood and hydrocyanic acid. These are the most immediate and powerful sedatives, in our acceptation of the term, yet each has its own peculiar mode of reducing irritability and vascular excitement, nor do they modify irritability and vascular action alike. Each, however, as with all other Sedatives, depresses irritability and action, and this is the only strong point of resemblance. The special differences consist in the different modes in which each Sedative alters irritability and action in their kind (§ 854, 895-901; also Indexes, Alteratives). It is an ignorance or neglect of this philosophy, and too often a contempt of all inquiry into the modus operandi of remedies (shut out, indeed, by the prevailing chemical doctrines of disease), which leads to a vast amount of malpractice, and, in respect to the most important of the agents now before us, which has prompted the substitution, in otherwise enlightened quarters, of opium, digitalis, tobacco, aconite, veratrum viride (§ 891 c, 960 a, 1065) ay, even stimulants and tonics, for loss of blood and tartarized antimony, and often, too, where bloodletting is indispensable to life.—Note H.

Besides what has been now said of the more prominent distinctions among Sedatives, there are others less distinctly marked among such of the agents as are most nearly allied, as the Narcotics. These, however, have been already indicated under the subjects of Narcotics, Therapeutics, Vital Habit, &c. But it is more remarkable that some of the Sedatives which have no point of resemblance, except in their effects upon morbid conditions, bring about alterations, or changes in kind, of a corresponding nature; as loss of blood and tartarized antimony, for example, in their subversion of inflammation and fever. But the same remarkable characteristic is strongly pronounced among many other remedies; as in the control which Cinchona, Arsenic, and Cobweb exert over Intermittent Fever (§ 892 aa-c, 900, 904 c, &c.).—See Note Ee p. 1133.

§ 1057, f. It is commonly said that "Sedatives exert their effects especially upon the nervous system." But this is far from being the case with loss of blood and the antimonials, and only in a restricted sense as regards those agents which have the greatest relation to the nervous system. The nervous power is certainly involved throughout. But this is also true of all other agents whose effects reach beyond the direct seat of their operation. All exert their primary action upon the parts to which they are applied; and when the nervous power is brought into operation, it is, as extensively set forth in these Institutes, by a transmission of the remedial influences to the nervous centres, and a consequent determination of the nervous power either upon the organic constitution of the brain or of other parts. If the action be exclusively local, the nervous system participates only as a part of compound tissues, not by reflex action unless through local centres (§ 746 c). True, this doctrine has no relationship to those physical ones which render the Science of Medicine as simple and mechanical as the business of a shoemaker.

But, do not some of the Sedatives affect particularly the nervous system, its central parts especially, just as other agents affect particularly other parts, as cantharides the bladder, ergot the womb? &c. Certainly; and this is especially true of the Narcotics. In excessive doses their main fury is expended upon the organic constitution of the brain, and venous congestion of that organ is one of the invariable consequences. But this is effected through a very different process from what has been

hitherto supposed. The result is partly due to the reflex action of the nervous power, in a modified condition, upon the capillary vessels of the brain and spinal cord, but also more or less upon the heart, the stomach, &c. (§ 228, 230, 508, 509, &c.). The intensity of the general effects upon the system at large will often depend more upon the determination of the nervous power upon important organs remote from the brain, than upon the amount of influence exerted by the nervous power upon the organic properties of the brain and spinal cord. The general reflex action may be so sudden and violent, as in the case of hydrocyanic acid, that it shall destroy the life of the heart, the lungs, &c., without leaving a trace of its influence upon the brain; as is seen, also, in sudden deaths from blows upon the epigastric region, surgical operations, &c. (§ $476\frac{1}{2}h$, 508-510, 828c, 904b). At other times, as with opium, the remote effects may depend much upon the morbid change which the agent may establish in the nervous centres. But, in its ordinary medicinal doses, opium exerts no such morbific effect upon the nervous system; when it rouses and modifies the nervous power in degrees of intensity which are not morbific (if the remedy be properly adapted to the pathological conditions), and in the same general way as all other remedial agents, but in a way, also, both as to degree and modification of the power, peculiar to the virtues of the narcotic (§ 227-229, and references there). It is this special modification of the nervous power, and its reflected alterative action upon various parts, which lessens and otherwise modifies the irritability, sensibility, and, of consequence, the organic actions, of all parts of the body (§ $891\frac{1}{2}k$, 893 a, c, 904 a, b, 1059).

§ 1057, g. Cold is generally local in its operation so long as it is confined to a limited portion of the surface of the body, and it is scarcely beyond this local effect that its operation as a sedative is witnessed. reflex nervous actions are mostly of a stimulating nature. In its local aspect it operates alone upon the organic constitution of the part, as seen in its effects upon superficial inflammations. But there are remarkable reflex influences, as when a current of cold air striking the neck or chest occasions rheumatism, catarrh, pneumonia, &c., or when exposure of the feet to cold arrests menstruation.* There is, also, a still more remarkable and very uniform effect of this reflex nervous action, but not of a morbific nature, in suddenly increasing the excretion of urine; and if with this phenomenon be associated the powerful effect of fear as a diuretic (§ $892\frac{3}{4}b$), there will be seen a display of results which demonstrate the analogy between physical and mental causes and the nervous power, and how the latter is developed by the former and participates as an exciting or modifying cause in all the remote effects (§ 224-227, 233 $\frac{4}{5}$, 475 $\frac{1}{2}$, 493 cc). Again: when cold operates with great intensity upon the whole surface of the body it occasions lethargy and venous congestion of the brain. The philosophy is the same as when hydrocyanic acid produces cerebral congestion. (See Essay on the greater action of Cold, in Med. and Physiolog. Comm., vol. ii., p. 590-602.)

The great variety of effects which Cold is capable of producing, besides those to which I have adverted, such as its invigorating influences when applied in the form of a shower-bath, both in health and many chronic maladies, &c., are among the plain things which illustrate the important agency of the nervous power in transmitting the influences of remedial agents from the direct seat of their operation to distant parts, and show us how readily and with what intensity this power may be brought

^{*} See also Brown-Séquard's experiment of immersing the hand in cold water, p. 807, \S 1044.

into operation by any of the substantial agents of the Materia Medica, or by morbific causes, while its universal manifestations in healthy states of the body, or as disease of one part gives rise to disease in other parts, establish the philosophy of our whole subject upon one common physiological ground of alterative reflex actions of the nervous system.

§ 1057, h. I have placed Tartarized Antimony in a subdivision by itself, though many would probably arrange it with the Nauseants. But the former produces very powerful sedative effects without exciting nausea, as seen in the manner in which inflammations and fevers yield to its quiet influence. But the principles concerned are exactly the same in all the cases; though great variety arises throughout the whole, even in respect to each individual agent, and according to its dose, the frequency of administration, the precise pathological condition, the nature of the organ affected, and many other modifying contingencies. As it respects Tartarized Antimony, its influences involve a very important modification of the simply sedative principle. This is its alterative power, and by which it is rendered of the highest value in the treatment of diseases (§ 150–151, 841, 857, 863 d, 892½ g, 902 g, 904 bb, 476½).

§ 1057, i. Finally: the group of Sedatives is designed mainly to bring into connection a number of remedies which have certain important analogies, but variously and often greatly distinguished from each other, that they may be considered comparatively; with a view to enlarging our knowledge of the relationship of remedies, their points of difference, their modes of operating, &c. It is, however, more artificial than any other

group, and is of very little use for practical purposes.

The Sedative Effects of Cotton-wool and of Castor Oil.

\$ 1057, k. In connection with the foregoing subjects, I shall briefly indicate certain apparently sedative virtues belonging to common Cotton and Castor Oil, as resulting from my own experience.

In the edition of my Materia Medica and Therapeutics of 1848, I re-

marked that

The virtues of *Cotton-wool* appear to be more than of an ordinary mechanical nature. It is evidently alterative as well as quickly sedative; and, doubtless, these remarkable effects are owing to some very peculiar mechanical influence. The Author has employed it with the happiest effect in poisoning by the Rhus toxicodendron; particularly in his own person, where the hands and arms were severely inflamed, swollen, and deeply ulcerated. The relief from suffering was immediate, and the dressing was not removed till restoration had become complete. The case had baffled other remedies.

I know not whether the remedy has been submitted by others to trials beyond its well-known uses in burns and scalds, excepting by Mr. Jones in cases of ulcers, who appears to have derived the same benefit from it

as myself (in London Lancet, Dec., 1850).

Very lately I had in charge an obstinate ill-conditioned ulcer upon a highly varicose leg of a lady of delicate health, attended, also, by an intense cutaneous inflammation surrounding the central half of the limb from the knee to the ankle, and which was studded over with a crop of suppurating eruptions. There was also a painful sense of burning and itching. Failing of all relief from the usual remedies, excepting a moderation of the sense of burning and itching from cold bread and milk poultices, I resorted to the cotton-wool, the effect of which was rather

astonishing. The painful sensations were immediately removed, and the cure completed in about a week, though a dry, thick, hard scab had then formed upon the ulcer, which became detached in five days afterward, when an elastic silk stocking was applied to the varicose limb. This occurred in the hot weather of June.

A large mass of the wool should be applied, so as to form at least an inch in thickness when bound down by a bandage; and thus far in my experience it should not be disturbed till there is reason to think that it has fulfilled its purpose. But, having never been in pursuit of new remedies, my experience in this particular is less than it otherwise would have been. I think, however, that there can be no doubt of the great superiority of cotton-wool to other means in the foregoing and analogous affections, even if it be necessary to remove the dressing frequently, as in cases of inflamed and chapped nipples. But even in these cases the cotton should be closely applied by means of a bandage. In the case of ulcers, it appears not to be of much importance that they should be in a favorable state for healing, though I regret that I have not tried the remedy in any of an eroding or malignant nature. It should be said, however, that the co-operation of constitutional means must often be necessary in the unfavorable cases which are not malignant, and that

in the latter we may hope for only a palliating effect.

§ 1057, l. Of Castor Oil I remarked, in the same work, that the Author called the attention of the Profession to the special alterative influences exerted by Castor Oil upon the Liver in his Letters on the Cholera Asphyxia of New York, and again in the Medical and Physiological Commentaries, and the alterative virtues of this remedy appear now to be extensively appreciated. I also said that, when frequently repeated (as every day, or every other day), it is commonly necessary, and pretty early, to reduce the quantity from one or two table spoonfuls to a teaspoonful, or even to a fourth of a teaspoonful, the remedy being remarkably cumulative in its effects. This is greatly owing, however, to the specific action of Castor Oil upon the Liver, and the consequent increased production of bile. It is often peculiarly efficacious when exhibited a few hours after calomel or blue pill; is very useful to overcome habitual constipation, on account of its alterative action upon the Liver, when it should be given in small doses every evening (§ 556 b, 889 m, mm). Other comments follow upon its important uses as a cathartic for children, and for pregnant women, and in dysentery, scarlet fever, chronic hepatic affections, &c., and after convalescence from acute diseases, but always in such carefully regulated doses as shall not produce intestinal pain and mucous discharges. When thus regulated in dose, its specific action upon the liver in inducing a free secretion of bile is greater, in a general sense, than calomel or blue pill, and very often more usefully alterative (\$ 857). It cannot be too strongly insisted that the dose should be accurately adjusted to the existing condition of the intestines. If it produce griping, or frequent or mucous discharges, the dose has been too large, and the useful effects of the remedy will have been lost, or disease may be aggravated, especially if seated in the alimentary canal.—See, as to mercurials and the liver § 1058 b.

I now come to the special object of this paragraph—the soporific virtue of Castor Oil, and this I shall present in an extract from my Lectures.

There is another remarkable peculiarity about Castor Oil, which, like

its special action upon the liver, and its cumulative effects, you will not find in the books. It is that of exerting a soporific influence; often calming restlessness, both in children and adults, soon after its exhibition. Nor does it, like many other cathartics, excite the general circulation in active forms of inflammation and fever, where bloodletting is not premised, if given in proper doses (§ 871). And, on account of its anodyne and soporific effects, I often exhibit Castor Oil in the evening in cases where I should delay all other cathartics, unless the mercurial, till morning (§ 863 d, 889 n). But it should be borne in mind that Castor Oil, in full doses, is apt to operate within four or six hours after its exhibition, and therefore, if given early in the evening it should be in such moderate quantities as may not be likely to disturb the rest of the patient by its cathartic effect before morning (§ 889, n). Having always observed this precaution in my practice, I have generally left instructions to repeat the same dose if necessary, or often a smaller one, at some hour in the morning, or, perhaps, only an enema of warm water. I have thus found the dose administered in the evening to have been very useful, though it have not operated as a cathartic. At other times, both in acute and chronic diseases, I have administered small doses of the Oil (as a teaspoonful or less), at intervals of four to twelve hours, with the intention of delaying a cathartic effect till some two or three doses shall have been administered—for the sake of its slowly alterative action upon the liver and intestines (§ 857, 859 a, b, 863 d, 873, 902 i, 905 a). This method is pursued in susceptible states of the intestines, and often in the advanced stages of all diseases, and during convalescence. The ultimate result is generally a copious production of bile.

ALTERATIVES.

§ 1057½. It will be seen, by referring to INDEXES, that the subject of this article has been variously discussed in its relation to particular remedies; and I shall now make some general remarks upon the group of Alteratives as assembled in the Author's Materia Medica and Thera-

peutics

Many of these agents are derived from groups that bear other denominations; as some of the best, for example, are included among the Cathartics and Emetics. But many of them belong alone to the group before us; and such of them as occur among remedies of other denominations are reduced to the group of Alteratives merely by their diminished doses and greater frequency of exhibition. And, although these last are, respectively, the same substances under different denominations, they are very different remedies, in certain practical respects, as they may stand in one group or another; though they may act upon disease in a more or less corresponding manner in whatever doses they may be employed.

But there is a general characteristic belonging to the so called Alteratives, as intended in this work, which assembles them into a group. That characteristic is their insensible operation compared with the members of other groups; and their action is to be appreciated only through certain inconsiderable phenomena, and through the subsidence of disease under their quiet influence—as when arsenic, or quinine, or cobweb operate in the cure of intermittent fever. When other remedies belonging to this group produce some prominent local effect, or are more serviceable in their operation in certain large therapeutical doses, they are,

in such cases, ranked under other denominations. Such is the case, for example, with tartarized antimony and ipecacuanha, which, in certain therapeutical doses, operate powerfully as emetics; whilst, in their acceptation as Alteratives, their doses are comparatively small and often repeated, so that they operate in an insensible manner, though their essential influence upon morbid states may be the same in whatever doses employed. In one case, or by their emetic action, they may produce sudden and great influences upon morbid conditions, alter them very speedily, and place them at once in the way of their natural return to a state of health. In the other case, or when employed in their small and repeated doses, they bring about the same salutary changes or alterations without exciting even any nausea (§ 516 d, No. 6, § 902 q). It is therefore evident that these substances, like many others of the group of Alteratives, may be, in reality, more immediately and profoundly alterative when employed in full doses, as Emetics for example, than in their small doses under the denomination of Alteratives. But it is also true that both tartarized antimony and ipecacuanha are curative of a vastly greater range of diseases in their small and frequently repeated doses than when administered as Emetics. It is also readily apparent that the same general remarks are equally applicable to calomel, blue pill, colchicum, &c., which are cathartic in certain doses, but powerfully, though more slowly curative in such small doses as do not produce purging, and which, therefore, in these small doses, I call Alteratives.

There are many things, however, which are as insensible in their operation as our group of Alteratives that are not included in this group, particularly the Tonics and Astringents. But the remedies belonging to these denominations are very peculiar in their effects, which are a good deal allied as the remedies may belong to one denomination or the other. This common characteristic serves, therefore, as a basis of arrangement for either group. But, in the case of the Alteratives, the want of any general correspondence in the immediate effects of its several members (with certain exceptions which are grouped into subdivisions), and the absence of any direct and well pronounced result, have led to this denomination.

It is thus seen that the denomination of Alteratives belongs properly to all positive remedies, since it implies the absolute effect of all agents that are truly remedial, whether physical or the salutary emotions. That is to say, they produce such alterations of the morbid conditions as enables Nature to accomplish the cure, or, more critically, the morbid organic states are so altered to a condition less profoundly morbid, as enables them to return spontaneously to their natural type (§ 853–856, 896–901).

Although, as we have variously seen, all agents which exert effects upon parts remote from the seat of their direct operation transmit their influences through reflex action of the nervous power, the Alteratives bring it into action somewhat differently from those agents which, like Catharties, and Emetics, and Loss of Blood, operate suddenly and with great power, especially when the Alteratives are administered in their usual small and repeated doses. They then develop the nervous influence progressively and continuously, and therefore bring about changes in the morbid states in a gradual manner; while in the other cases the changes are introduced abruptly (\S 222–233 $\frac{4}{5}$, 516 d, No. 6, \S 551, 552, 556, 841, 863, 867, 894–896, 902 e–g, 904 bb, 476 $\frac{1}{2}$ h, 905, &c.).

It will be seen, therefore, that the distinctions which are made of remedies into Cathartics, Emetics, Expectorants, Astringents, &c., are mercly arbitrary, and for the sake of convenience. As we have variously seen, also, Cathartics, Emetics, &c., do not primarily cure by the evacuations they produce, but essentially through their alterative action. The evacuations or redundancy of the secretions are only consequences of changes which the remedial agents effect by their alterative action (§ 863, 889 f-h); and while Cathartics, for instance, are employed in introducing such changes in the functional condition of the intestinal mucous membrane, those very changes lead to all the alterations which take place in diseased parts remote from the intestinal canal (\$ 889, f). Whatever part the redundant products may contribute towards the cure of disease, they are not only the result of the alterative action of the remedies, but their own tributary influences are of an alterative nature, and mostly through the same principle of sympathy that governs the remote action of the agents employed. It is the same as in § 944 c.

Many Alteratives, in the sense implied by the group now under consideration, are remarkably applicable to a vast range of diseases; but nearly all the diseases, to which any of the members of this extensive group are suited, are the various phases of inflammation and fever. Hence the group forms one of the Orders of the class of Antiphlogistics.

Those Alteratives which are of this universal nature I have assembled, in the order of their general therapeutic value, under the denomination of General Alteratives adapted to inflammatory and febrile diseases in a general sense. They are more or less suited to all the varieties of inflammation, whether acute or chronic.

There occurs another general assemblage which are more especially adapted to specific forms of inflammation and fever, and these are arranged under subdivisions according to the specific forms of disease for which they are employed, and in the order of their relative value. The following are the subdivisions:

1. Adapted to scrofulous, and some other specific chronic inflamma-

tions.

2. Adapted to syphilis, and certain other specific chronic inflammations.

3. Adapted to syphilis complicated with scrofula.

4. Adapted to rheumatism and gout.

5. Adapted to intermittent fever, intermittent inflammation, and other intermitting diseases.

6. Adapted to obstinate and chronic cutaneous diseases, carcinoma,

elephantiasis, &c.

Our class of Antiphlogistics embraces, also, a group of Alteratives which are designated as *local*, on account of, particularly, their application to the surface of the body. This, also, is an extensive group, and is divided into *Constitutional Alteratives*, or such as extend their effects by remote sympathy, and of which there are but few; and, secondly, *Limited Alteratives*, whose action is limited to the part to which they are applied, or extended only by *continuous* or *contiguous* sympathy (§ 497-498, 818½, 893, 905, &c.).

As all this practical grouping of remedies is relative to principles embraced in these Institutes, I formerly introduced the disposition which I have made of the Order in which the group of local Alteratives occurs. Unlike the Alteratives which are employed internally, the present assem-

blage does not appear as an order, but as a division under an Order of

Cutaneous and other Local Affections. (See p. 643, 644.)

These Alteratives (p. 643), which are employed locally, may operate either constitutionally, through reflex nervous influence, like the internal alteratives, as the mercurials, or in a more circumscribed manner through the ganglia or other centres of the sympathetic nerve, or only superficially, as with Suppurants, Escharotics, and Sedatives; but Vesicants, which are embraced in the group, always exert useful effects upon internal maladies through reflex action of local nervous centres (p. 642-648, § 893 α -f, p. 652–655, § 893 m, p. 657–659, § 893 p, p. 679–681, § 905 a). Other remedies included in the group must also operate upon internal parts through local centres of nervous influence (§ 497, 1038), such as Aconite in the relief which it affords to neuralgia. I have relieved a very painful neuralgic affection of the whole extent of the sciatic nerve in fifteen minutes by rubbing along its course an ointment of aconitin, which had refused to yield to other remedies.-The extensive subdivision which is designed for diseases of the skin supplies examples of a purely local action upon the organic properties of the part without the auxiliary aid of nervous influence (§ 658). Some of them, however, will also exert constitutional effects through reflex nervous influence, such as the mercurial ointments (§ 514 d, 826 d, &c.). Remedies of that nature, therefore, are arranged also in another subdivision, indicating their extensive constitutional influences through the medium of the skin and nervous system (§ $891\frac{1}{2}g$, 893 a, 1059, 1088 b, 904 b).*

The foregoing details, and some others of a corresponding nature, are farther designed to exhibit the advantages of the Author's system of a

Therapeutical Arrangement of the Materia Medica.

 $\S 1057\frac{3}{4}$. I shall now introduce a series of important remedies, not only for the purpose of examining their special uses, but particularly for a farther illustration of general principles in Medicine, and the Philosophy of Organie Life, for which this work is especially designed ($\S 1062\frac{1}{2}$).

CHLORIDE OF MERCURY, AND THE BLUE MERCURIAL PILL.

§ 1058, a. I shall speak mostly of Calomel as employed in full doses for its cathartic effect; and this for the purpose, especially, of indicating its remedial virtues. Its smaller and more repeated doses, however, will be the subject of remark; though, in whatever doses exhibited, it is its alterative action which bestows the service (§ 889, a-g), which, indeed, is true of most other remedial agents (§ 516 d, No. 6, § 638, 863 d, 896,

900, 902 g-m, 904 d, 905, and INDEXES, article Alteratives).

I need not say that Calomel is rarely actively purgative, although it occupies the first rank among Cathartics in my Therapeutical Arrangement of the Materia Medica, or that, to procure a cathartic effect, it is commonly associated either with Jalap, Aloes, Rhubarb, Podophyllum, Colocynth, Scammony, Gamboge, or Extract of Butternut, or, if exhibited by itself, some other cathartic is generally prescribed within a few hours afterward. The combinations, too, with the several articles are most useful, in a general sense, in the order in which I have now stated them. Thus, Calomel and Jalap are more extensively useful than Calomel united with any other cathartic. Podophyllum resembles Jalap in its action, but is much inferior; so that Aloes is the next adjunct on account of its adaptation to a great range of chronic affections of the di-

gestive organs, and next Rhubarb, and so on; and it is well known that it may be often useful to blend two or more of these together along with the calomel. But the merits of each individual case should, of course, be brought to bear upon the right combination at the time of prescribing

(§ 150–151, 857, 870 a, b, 872 a, 888 a–c, 1061).

As I shall soon set forth, however, it may be often most useful to exhibit Calomel uncombined, and to administer some other cathartic at an interval of some hours afterward. For this purpose Castor Oil generally surpasses all others (§ 1057, l); and, next to this, in a general sense, we may reckon Jalap combined with Tartrate of Potash (§ 1060); and next, the neutral saline cathartics (§ 1061); and next, Rhubarb along with Calcined Magnesia and the Tartrate of Potash and Soda (§ 872 a, 1061). We need rarely go beyond the cathartics which I have now mentioned, as ultimate aids to Calomel, with a view to purgative effects. But it should be always considered that it is the alterative action, the direct influence upon disease, that is to be chiefly regarded in the choice of these remedies, and of none is this so true as of Calomel. Hence it is evident that the precise circumstances of the disease must determine the choice (§ 872 a, 883 a, 888 b).

But, though Calomel be not actively purgative, it is powerfully alterative, and, in doses that are felt, it is never negative in its effects. It alters the condition of disease either for the better or for the worse—too often for the worse (§ 854). There is no other remedy that requires more skill for its right administration—none, with the exception of loss of blood and tartarized antimony, that reaches more profoundly diseased conditions, or which will so often turn them to health, when wisely employed. And so, on the contrary, it is capable of inflicting great injury

· if not suited to the case.

§ 1058, b. Let us then consider, in a general manner, some of its useful effects when employed in full purgative doses. Its action is mostly exerted upon the stomach and duodenum. Here its first great curative impressions are made, and from these parts powerful reflex nervous actions radiate over the whole system, though more so upon some organs than upon others. Its effects are most strongly pronounced in some of the glandular organs, especially the liver; and hence it is peculiarly suited to diseases of that organ in many of their phases. But its action upon this, and other parts remote from the stomach, will depend upon the manner in which they may be affected by disease; for we have variously seen that the susceptibility of tissues to the action of remedies is not only increased by disease, but will be influenced by its exact condition—than which there is nothing more important to be known (§ 129 h, i, 134, 137 d-151, 240, 334, 556 c, 650, 662, 674 d, 675, 854 bb, 855, 859, 870 aa, 871, 888, 892 c, 892 $\frac{1}{2}$ a, b, 892 $\frac{1}{5}$ d, 970 c, 1063 b).*

When the whole system is invaded by disease, as in idiopathic fever, we may anticipate a universally favorable impression when this remedy is rightly applied; and this, too, whether employed in its largest or its smallest therapeutical doses—though, as a gradual alterative for this purpose, Tartarized Antimony is much better (§ 148, 557 a, 841, 892 c, 900, 902 i; and Indexes, Alteratives). When active inflammation affects any part, we may generally calculate, if there be no objection to its use, that a few grains of Calomel will reach that part advantageously, especially if Blood-letting have been premised (§ 672, 868, 871, 889 g). And yet, under circumstances of health, the same dose might have no

^{*} Calomel and blue pill rarely increase the bile in health. Hence the great fallacy of Dr. Scott's late experiments with mercurials upon healthy dogs (§ 694 b, 837 cc, 854 bb).

effect upon the same organ. This, however, is constantly more or less true of all other remedies.

We have thus before us two great leading facts—that, in fevers, and acute inflammations, especially if the latter affect any important organs, the next great curative means after bloodletting, if the latter be required, is, in a general sense, Calomel, in at least one dose, with a view, in part, to a cathartic effect, though carefully regulated as to quantity. Whether a full dose should be repeated, or whether in any dose, and with what frequency, will then depend upon the peculiarities of each case. The general affirmation can be made with greater certainty, that one full dose will be proper and useful in the early stages of disease, than we can pronounce upon the probable advantages of its repetition. But, it is a very common circumstance, where it may be inexpedient to carry this remedy beyond one or two full doses, that Blue Pill may be afterward exhibited with happy effect, when the continued use of Calomel would have been injurious.

§ 1058, c. This correspondence between the virtues of Calomel and Blue Pill leads me, now, to speak of them comparatively. Notwithstanding their affinities, they are well known to exert effects which distinguish them from each other. But this difference consists mostly in the effects of one being more rapidly produced, and more strongly pronounced than those of the other. Calomel is more irritating, rapid, alterative, and positive in its action than Blue Pill; while in other respects, the general results of both are greatly analogous. The resemblances and differences in their effects may be farther illustrated by comparing them, respectively, with general Bloodletting and Leeching (§ 925,

927 a, 929, 939 e, f, 956-958, 966, 968, &c.).

From these analogies in their useful effects, and from their powerfully alterative virtues, it is evident that the same coincidences will be likely to obtain in their bad effects (§ 854 c d, 857); and such being the case, whatever I may say of the injurious effects of Calomel, and of the precautions which should attend its use, will be equally applicable, though

in an inferior degree, to Blue Pill.

§ 1058, d. It is a well-ascertained fact that, in numerous cases, Calomel and Blue Pill have not their effects increased, beyond a certain quantity, in the ratio of the increase. Ten grains of either will often produce as great a cathartic effect as fifteen grains; or, at least, this is inferable. Beyond fifteen grains the difference is still less manifest. But below ten grains this ratio is less likely to appear; though five grains will often operate with greater effect, in proportion to the quantity, than ten grains. Nevertheless, the difference between five and ten grains, and at other times between two and five grains, is so considerable that the smaller quantity may be very beneficial when the latter would be very injurious (§ 857).

But there are occasionally some very remarkable peculiarities in the effects attending the smallest and the largest doses of Calomel, when they are regulated according to the repute which Calomel holds as a cathartic, and which are but little observed of Blue Pill. When employed, for example, in very large doses, even far exceeding the largest in common use, the cathartic effect is wholly counteracted by the peculiar nature of some present intestinal disease; or the dose may even arrest diarrhæa, as Calomel often will, also, when employed in the minute doses of a fourth or tenth of a grain. In respect to the large doses, I will quote an

example which occurred at one of the London Cholera Hospitals in 1832, where Mr. Bennett is said to have treated successfully 17 of 18 cases by exhibiting to each patient, as soon as admitted, 120 grains of Calomel, and afterward 60 grains, every hour or two, until some relief was obtained. Several of the patients took from three to four ounces. Its direct effect was that of restraining the vomiting and purging. These 17 patients recovered, and the record so far is undoubtedly true; but, from what we know of the fatality of the malignant cholera in the hands of others, after the accession of those symptoms which are diagnostic of the disease, we are bound to believe that, in most, and probably in all, of these cases there existed only the premonitory stage, as it is called, when the disease is always very easily controlled, and by much milder treatment.

It has been long known that large doses of calomel—such as 20 or 30 grains— will arrest vomiting and diarrhea attendant on particular pathological conditions of the intestinal mucous membrane. This it does in virtue of its profound alterative power, and shows us that it is the alterative, and not cathartic, operation which contributes essentially to the cure. It equally denotes, also, an error in the imputed sedative effects of the remedy, as will be more distinctly seen in the entire failure of such doses, and of others far more moderate, in the ordinary forms of diarrhea and vomiting, and in cholera morbus and cholera infantum. But, in these last cases, particularly in cholera infantum, and often in dysentery, we may obtain the greatest benefit from small doses of Calomel—doses, when administered in cholera infantum, varying from the fourth to the twentieth part of a grain. All of this, too, goes to demonstrate that it is not the cathartic, but the alterative virtues of Calomel which impart to it its remedial power.

These facts admonish us that we must study the virtues of remedies, and their doses also, in their relation to diseased conditions, and that we can form no just conclusions as to their remedial capabilities by any other methods of observation, and, above all, that we have nothing to

hope from Organic Chemistry (§ 1058 b, note).

§ 1058, c. Although Calomel and Blue Pill are capable of profoundly morbific effects in many forms of disease, unless they have been preceded by other remedies, especially in miasmatic congestions of the liver and intestinal mucous membrane, where nothing may follow their precipitate use but a discharge of viscid mucus, and an aggravation of all the symptoms, I shall not prolong this article by analyses which would involve so great an amount of detail. Nevertheless, it is impossible to arrive at any just conceptions of the virtues of remedial agents without referring to their effects in various conditions of disease; nor can we obtain any correct view of their remedial capabilities by considering the operation of a particular remedy abstractedly from other means which may be associated with it in the treatment. A full dose of Calomel, for example, may be very salutary in some given form of disease, if it have been preceded by Bloodletting, as is often witnessed in congestive fevers, but without which it may be very pernicious. At another time, its good effects, or at least its best effects, can be secured only by associating with it other remedies, or, by applying others after its administration. same, also, is more or less true of all other remedies; each one influencing, more or less, the effects of the others (§ 859 b, 863 e, 871, 872 α , 889 k).

§ 1058, f. In continuing the subject of Calomel, I shall now consider its uses in certain special forms of disease, when employed in its occasional and full doses:

And first of dysentery, which is seated particularly in the lower tract of the mucous tissue of the large intestine, though all the digestive organs are more or less involved in morbid action. But the burthen of the disease is upon the mucous membrane, where it probably consists at all times of a peculiar modification of inflammation, though differing, in different cases, according to the nature of its remote causes (§ 644–666).

Now, the treatment of this disease, not only by Calomel, but by other remedies, will be influenced by the nature of the remote cause; and this will be ascertained by the phenomena, and by tracing up the history of the patient for one or more months anterior to the attack. Its principal causes are, mainly, two: 1st, crude, indigestible food, acting in conjunction with changes of weather, and other common atmospheric

influences. 2d, miasmata, from decaying vegetable matter.

The first of these modifications is sporadic, and comparatively mild. The second may present only sporadic cases, but is apt to occur more or less epidemically, and is vastly the more obstinate and fatal form. Each variety demands essential differences in the details of treatment, though the same general principles are applicable to all the modifications. It should be also premised that the miasmatic form is attended with a special condition of hepatic congestion, which is one cause of the greater obstinacy and fatality of this variety of the disease, and which has a considerable bearing upon the treatment (§ 650–652, 806–816).

With these premises before us, we are now chiefly interested about the adaptation of Calomel to dysenteric disease, with a view especially to its local effects. But, it is impossible, as I have said, to give any intelligible account of the proper use of one remedy, especially such a remedy as Calomel, without speaking of it in connection with other remedies which may, or should be, associated with it. We have formerly seen that, when active inflammation is seated in the intestinal canal, cathartics are hazardous till the disease has been more or less subdued by other remedies, especially Bloodletting. Calomel, however, does not irritate in the same way as other cathartics. But it will often do what is much worse in muco-intestinal inflammation. It may not only increase its severity, but so modify its character as to render it very malignant, as in another example of a common abdominal affection to which I have adverted, and also in scarlet fever. In such circumstances, it never fails to affect the liver injuriously also. It has been therefore found, in the best experience, to be the most successful and speedily curative practice to abstract blood from a vein, or at least by Leeches, as the first remedy, in cases of dysentery of much severity (§ 991, b). But this is not commonly done, and Calomel is apt to be relied upon as the principal remedy. It is a prevailing practice to exhibit, at the onset of the treatment, from 10 to even 20 grains of Calomel, and not unfrequently to repeat this dose from time to time. When the disease is of the milder variety, if other things go right, it will often succeed in the end; though not so readily, and less frequently than when Calomel is given in doses of two to five grains once in twelve or more hours; and, in many cases, a grain or less of Ipecacuanha, also, once in four or five hours, with more or less of some preparation of opium. A large medication by Calomel in any condition of dysentery is not a reliable, but

often an injurious practice. When proper bloodletting has not been employed, if the inflammatory symptoms do not soon yield, all internal means should be suspended, and General Bloodletting, or Leeches to the verge of the rectum, or a blister, or warm poultices, to the abdomen, should be applied, and perhaps in succession. Alterative doses of ipecacuanha may often become very useful, perhaps Blue Pill, but more

probably well-regulated doses of Castor Oil (§ 1057, l).

So much for the milder, or sporadic form of dysentery. Coming to the miasmatic variety, especially when prevailing epidemically, the Practitioner who does not regard the modifying nature of the remote predisposing cause, and the exact pathology, will prescribe empirically, and be apt to administer large doses of Calomel, which, in this condition of the disease, will be very likely to destroy the patient. Or, if he depend upon astringents, or administer Rhubarb as is often done (§ 1062), or resort to Tonics and Stimulants, nothing but disappointment will await him. General Bloodletting, often followed by leeching, is here the great remedy. But, however we may subdue the morbid condition by loss of blood, with the aid, also, of blisters, abstinence from food, &c., we shall generally find that Calomel must be managed with great prudence, or the disease will not only be aggravated by it, but rendered more malignant.—Notes Ff p. 1135, Gg p. 1138.

As to Loss of Blood, Nature also proclaims in this variety of dysentery, more distinctly than in the sporadic, the true principles of treatment, for here the effusion of blood from the intestinal mucous membrane is greater; and this is plainly the remedy which Nature institutes for

her own relief (§ 805, 862, 863 e, f, 890 d-g, 1019).*

\$ 1058, g. In respect to fever, most of its varieties derive, at their early stages, great benefit from a full dose of Calomel combined with Jalap and a grain or two of Ipecacuanha; or it may be most useful, in many cases, to exhibit the Calomel uncombined, and to administer Castor Oil, or a combination of Jalap and Tartrate of Potash, a few hours afterward. If an emetic be also indicated, a full dose of Ipecacuanha, perhaps with Tartarized Antimony, may be preferable to the latter remedies; so that when vomiting begins, purging will generally take place simultaneously. In this way prodigious alterative influences will be exerted, and if employed near the invasion of disease it may be arrested at once (§ 557 a). But it often happens, as has been variously stated in this work, that bloodletting should be premised, and this, especially, if there be any local inflammations or venous congestions, which are often present at the invasion of the constitutional malady.

§ 1058, h. When Calomel is employed in the treatment of Scarlet fever, it should be with great caution after the disease has advanced somewhat into the eruptive stage. At this period, Calomel, Senna, and Rhubarb have done a vast amount of mischief. At or near the invasion of Scarlatina, when the symptoms are severe, a moderate dose of Calomel may be useful. Nevertheless, severe forms of this disease not unfrequently occur in which Calomel, administered at the very onset of the attack, proves detrimental. If doubt exist as to the propriety of the remedy, Castor Oil should be substituted, and perhaps little else should be done (§ 858, 861). It may be also safely affirmed that Calomel should be rarely exhibited after the disease has run its course for some two or three days; not often, indeed, when the eruptive stage has existed for twenty-four hours. It will then aggravate the abdominal conges-

^{*} In mild forms of dysentery there may be an absence of blood, or the mucus only tinged.

tions, and often convert a mild into a malignant form. And here, too, when Calomel affects the digestive organs perniciously, the salivary glands often swell up suddenly from sympathy, and, not unfrequently, the throat becomes ulcerated, gangrenous, &c. But these are only secondary results of a far more alarming condition of disease in the abdominal organs. The swelling of the glands, in these cases, is not at all owing to the direct specific effect of mercury upon them, as in cases of salivation, nor is there any attendant flow of saliva; but it is the result of a highly aggravated state of the morbid condition of the abdominal organs, inflicted upon them by this remarkable agent. The glandular swelling which often occurs spontaneously from the same visceral cause, presents a far milder form. There is not generally, however, much danger from the swollen glands, or from the sphacelus of the fauces, so only they be not allowed to remain a source of constitutional irritation. One may be relieved by a stick of lunar caustic, and the other moderated by leeches and warm fomentations. What is thus witnessed about the throat is only an index of a far more fearful evil in the great organs of life. In these cases Nature, mainly, must work out the cure (§ 816 b.)

For the grave forms of Scarlatina, I am apt to prescribe a small dose of Calomel at the beginning of the disease, but never repeat it; and as for the rest, I depend upon cautious doses of Castor Oil, as far as may

be indicated by the state of the abdominal viscera (§ 1057, l).

I may finally add that, in all mild cases of scarlet fever, no risk should be taken from Calomel. It is not then wanted; and I have seen the mildest converted into malignant cases by imprudent doses of Calomel, and by Senna, Rhubarb, and the Saline Cathartics. Indeed, so susceptible is the alimentary mucous tissue in this disease, and so peculiar is its morbid condition, that solid food, even bread, will sometimes convert the mildest into the severest cases, merely by its mechanical irritation. It should be also borne in mind that in this, as in all other strictly self-limited diseases, we cannot establish any modification of the pathological cause which will prevent its running a regularly ordained course. The natural state of these affections, in all favourable cases, is most likely to result in their cure (§ 858, 861). In the graver forms, art can only moderate their violence, or meet with appropriate remedies any incidental local inflammations that may spring up in the progress of the specific maladies (§ 137 c, 524 d, 847, 858, 870 aa).—See P.S. 1860, p. 872.

§ 1058, i. As to the treatment of measles and small-pox, I do not recollect to have witnessed any injurious effects from the use of Calomel, nor do I find them stated by Authors. Perhaps one reason is, that Nature has been more allowed, in these self-limited diseases, than in scarlatina, to have her own way. But here the danger from Calomel is certainly

far less than in scarlet fever.

§ 1058, k. In whooping-cough, Calomel, as a cathartic, or rather for its alterative effects upon the abdominal organs, is often very salutary; and this especially so when the alvine evacuations present a morbid appearance. Blue Pill, however, is often better. Bloodletting should come in the moment that pneumonia may supervene, as it often does, and is the great cause of the fatality of whooping-cough (§ 870, aa). But here, as in other acute diseases, great moderation as to food is powerfully curative (§ 856).

\$1058, l. In the ordinary forms of jaundice, whether complicated with a gall-stone in the liver, or owing alone to hepatic disease, Calomel dis-

plays some of its brightest advantages, and may be given, if apparently indicated, in doses of 10 to 20 grains, two or three times a day, with jalap, or, perhaps, aloes, or the resinous cathartics, at intervals, till the difficulty is more or less surmounted. But Jaundice is often of too grave importance to be always intrusted to those remedies; and Bloodletting must then be the principal remedy, followed, perhaps, by a blister eight or ten inches square over the epigastric region. If there be gall-stones,

Cicuta may be useful in relieving spasm of the biliary duct.

\$ 1058, m. Calomel is an admirable remedy, as it respects its transient effect, in erysipelas, a disease which is often sadly managed by tonics and stimulants (\$ 1005, j). The least important part of the disease is also generally considered the most important, since, in all severe cases, the inflammation of the skin is comparatively of little moment. Now and then, however, when erysipelas springs up epidemically, the superficial inflammation puts on the phlegmonous character, when ulceration and sloughing are apt to follow; and these conditions, as well as the antecedent and remaining inflammation, form an important part of the pathological complications. But of the pathology of this disease I have spoken sufficiently (\$ 970 c, 1005 j), and therefore come to the treatment.

The great curative means, in all severe cases, is early and full Bloodletting, followed by five to fifteen grains of Calomel, and this in six or eight hours afterward by Jalap and Soluble Tartar, or by Castor Oil. If, by these means, a blow be struck at the abdominal disease, the inflammation of the skin will begin to give way, and nothing more may be necessary than, perhaps, a moderate dose of Calomel, or of Blue Pill, or, more probably, Castor Oil, or Leeches to the inflamed surface. Or, Nitrate of Silver, pure and concentrated, or dilute Iodine may now be pencilled over the whole inflamed surface. But, for subduing the remaining inflammation, Leeches are the best local application, in my experience, and they are dictated by the soundest pathological principles. Nevertheless, whatever is done in severe cases should be done quickly; and, if the treatment have failed, at the onset, to sensibly mitigate the symptoms, especially the cutaneous inflammation, which is only symptomatic of abdominal disease, we may depend upon it that the latter condition calls for farther general Bloodletting, and probably for another dose of Calomel, or at least of Blue Pill, and more or less of Castor Oil. If cerebral symptoms (which are also sympathetic of the abdominal congestion) spring up, a large abstraction of blood will be indispensable.

I have never known Calomel injurious in erysipelas; but it must be added that I have almost always begun the treatment by abstracting blood, which, as I have said, is a great means of preventing the morbific effects of Calomel and Blue Pill; and no fatal case has occurred in my

practice (\S 1005, j).

§ 1058, n. And now, as to acute rheumatism. Here, too, in all severe cases, especially of articular rheumatism, there is much attendant disease of the abdominal organs, which contributes powerfully to maintain the rheumatic affection; and it commonly happens, in such cases, that, after the inflammatory condition is subdued, there will be still remaining a considerable amount of visceral disease, which will require, at least, great simplicity of diet. In all severe cases, it will be often observed that the abdominal affection precedes the rheumatic, but becomes much aggravated as soon as the latter supervenes.

Calomel is a very useful remedy in acute rheumatism, in one or more

full doses, or yielding soon to Blue Pill, or Castor Oil, and rarely does any harm. But, in all severe cases, a free abstraction of blood should be the first remedy; and one or more repetitions of venesection, along with leeches perhaps, are often important to a speedy removal of the disease, and a fluid farinaceous diet is next in importance. Any other practice which excludes Bloodletting in severe cases will be more profitable to the Physician than to the Patient. The next great remedy for acute rheumatism, and often for chronic, is Tartarized Antimony, frequently administered in augmented doses to just short of nausea. If the heart be affected, the Loss of Blood will be so much the more important. In a large proportion of cases, the disease will yield to this practice within a week. But, however exact the treatment may be in other respects, an allowance of solid food, even bread, or of animal broths, may prolong the disease, especially the abdominal derangement, for many weeks. Colchicum should not be necessary in the declining stages, nor should opiates be employed (§ 870, b).

§ 1058, nn. The same general principles of treatment apply to acute gout as to acute rheumatism (§ 1058, n), though in a moderated degree. A full dose of Calomel, or of Blue Pill, is generally useful at the onset of the treatment, one or the other, according to the derangement of the abdominal organs. But here, if the paroxysm be at all severe, and we would most speedily relieve the patient, he should be first bled. Lastly, if necessary, and often pretty early, Colchicum may be exhibited.

§ 1058, o. In pneumonia, Calomel or Blue Pill, in one or more full doses, at or near the beginning, is generally useful, rarely injurious. But it is sometimes a better practice to obtain more of their constitutional influence by exhibiting from one to four grains of either (to adults) once in four to six hours; though this is by no means recommended as a general practice. It is better suited to advanced stages of pneumonia. If complicated with abdominal disease in the form of bilious pneumonia, they are still more indicated, but unless cautiously administered are liable to do injury. Bloodletting, however, is the great remedy for all forms of pneumonia, and next to that Tartarized Antimony, in increased alterative doses every hour or two, but kept below the point of nausea (§ 904 bb, 1005 k, 1068 c). Leeches and Blisters may ultimately be wanted, and perhaps more or less opium to tranquillize the cough, as appears in other places (§ 892 $\frac{4}{5}$ g, 1005 h, k, 1017 c).

§ 1058, p. In the treatment of croup, which is apt to be complicated with abdominal disease, a dose of Calomel is generally useful, often very important. I generally exhibit it, in a moderate dose, along with sufficient Ipecacuanha to produce vomiting. If the symptoms do not then yield, I take no risk, but proceed at once to the abstraction of blood from the arm (§ 576 e, 1009-1013). There is no danger from the ordinary forms of croup when Blood-letting is applied early. But the disease advances with great rapidity, and may quickly reach a stage when all remedies will fail. If late in the disease an emetic be the first remedy, it will certainly fail if blood-letting will not succeed; or, if the latter, in being first, will effect a cure, it would be probably baffled by the prostrating effect of a preliminary emetic (§ 576 e, 869). I may add that I have lost but one patient of croup, and that in the early part of my professional life. It is of greater interest, however, that the child was rather the victim of the purgative action of Tartarized Antimony, administered in cautious doses about once in twenty minutes.* The croupy

symptoms vanished under this effect; for there was no vomiting. I have also witnessed the death of two adult patients in the hands of other Physicians from the same cause, and where the doses given were but three grains. There was no vomiting, but an uncontrollable watery purging, no abdominal pain, pulse extremely rapid and so small as to be scarcely sensible to the touch when there was much remaining muscular strength, and entire preservation of the mind (§ 863, d). Nevertheless, this has not deterred me from the occasional use of Tartarized Antimony in emetic doses, especially in conjunction with Ipecacuanha (§ 675, 857, 902 g, &c.); and as an alterative in small and frequently-repeated doses it transcends the Mercurials in fevers, and is scarcely inferior in all acute inflammations excepting of the intestinal canal.

§ 1058, q. And how is it with Calomel in acute inflammation of the brain? Certainly important. But after one full dose it becomes most useful in doses of two to four grains once in four to ten hours. This, however, is more of the gradually alterative plan, and when more of the constitutional influence of the remedy is intended than we are now considering, especially if all purgative effect be restrained (§ 516 d, 860, 863 d, 890 l, 902 i). There should be no active purging in cerebral inflammation by irritating cathartics, as is often recommended in the books. They will propagate a pernicious nervous influence upon the brain. Calomel, Blue Pill, Jalap, and Castor Oil are alone wanted, so far as cathartics are concerned. The Drastics have been commended upon the fearful doctrine of counter-irritation, supplying an impressive contrast with the objections alleged against Bloodletting (§ 889 g, 893 n, 1065 d).

But, as I have hitherto said, Loss of Blood is our chief remedy in acute cerebral inflammation. So long as the symptoms continue to recur, they should be promptly met by General Bloodletting. Set the patient erect, and bleed him to the point of syncope. There is nothing to fear from the remedy, but every thing from the disease (§ 974–975).

Leeching, and Tartarized Antimony in its small doses, which are so valuable in other acute inflammations, are of little or no use here; and Blisters should be avoided till at least a decisive ascendency is obtained over the disease. The latter remedy should never be applied to the head, but to the neck and shoulders, unless the abstraction of blood have been carried to a great extent. In some four or five cases, after having bled the patients till the remedy became unavailing, I have rescued them by covering the entire scalp, neck, and upper part of the shoulders with a Blister. The effect was truly wonderful, as hope was nearly exhausted. But the Loss of Blood had been very great. I may add that the head should be shaved early and kept covered with ice (§ 992, 1056).

Nor may we refrain from general bloodletting in venous congestions of the brain, and at all ages, though generally in a very moderated degree (§ 576 e, 925 c, 976 b, 978, 1010. Also p. 872 P.S. 1860).

§ 1058, r. In respect to diseases of the serous tissues, they are probably less influenced by the mercurials than of most other parts. Neither pleurisy nor peritonitis are very sensibly benefited, nor are they apt to be aggravated by full doses of Calomel, unless it be inflammation of the serous coat of the intestines; and here there is but little chance for other remedies until the disease has been broken down by loss of blood (§ 960 f, 995, 1005 e).—Note H p. 1117.

§ 1058, s. Next, as to the kidneys. These and the renal capsules have become specialties with many, who are apt to mistake what is merely

symptomatic for some positive disease of those organs. The urine is analyzed, and a variety of pathological conditions are detected in the results, or some remote symptom is associated along (§ 426, 427, 691, $905\frac{1}{2}$ b, 960 c, d, 1029, 1032 a). Hospitals supply the bulk of disorganized conditions. Other affections of the kidneys, especially such as are acute, derive more or less benefit from the moderate use of Calomel; but Blue Pill is commonly to be preferred, particularly in diabetes mellitus.

§ 1058, t. Where inflammation of any of the tissues of the eye is complicated with gastric and hepatic disease, as is often the case, especially in epidemic ophthalmia, the occasional exhibition of Calomel, in a decisive dose, along with Jalap, or followed by Castor Oil, if necessary to a full cathartic effect, is generally very useful; and especially so if the ca-

thartic have been preceded by general or local bloodletting.

§ 1058, u. Next to bloodletting, Calomel, in full doses, is the most important remedy for apoplexy, along with Jalap, &c. But there is great variety here. There are cases in which no cathartic is admissible, and others where none but Croton Oil will rouse the intestines. For the

rest, I refer to $990-990\frac{1}{2}$.

§ 1058, v. Calomel, in one or more full doses, is indicated, generally, in epilepsy, if bloodletting be also necessary. But, if loss of blood be not required, Blue Pill is entirely preferable. Much will depend, in these respects, upon the condition of the abdominal organs. If there be much derangement here, a large blister over the epigastric region yields much relief, though these are cases which are often greatly benefited by Loss of Blood. A rigid attention to diet, and other natural habits, are the great preventive means. But a reliance is apt to be placed upon some fancied specific, and when the paroxysms come on the symptom is often in the ascendant (§ 163, 884, 887, $891\frac{1}{2}e$). I see, however, by a late Report of the Chairman of a "Committee on the effects of Bloodletting in Epilepsy, Convulsions, &c.," embraced in the able "Transactions of the Indiana State Medical Society," that a new view appears to be entertained of the pathology of Epilepsy, which brings the disease, theoretically and practically, under the prevailing Brunonian philosophy (§ 1068, a); and, as the document is brief, and is regarded by the Publishing Committee as a "Model Report," and, moreover, shows us what are the growing prospects of "Bloodletting," I shall quote it without abridgment:

"Having examined," says the Report, "the literature of the subject, I find that none of our recent Authorities have any confidence in Bloodletting as a remedy for Epilepsy, but, on the contrary, an opposite mode of treatment is advised, the disease being one of *debility* instead of plethora. The question being altogether a negative one, and unsuitable for a report, I wish to be discharged from farther duty."—Transactions.

&c., p. 8, 40, Indianapolis, May, 1857.—See p. 591, § 891½ e.

§ 1058, w. Asthma supplies another example of greatly modified conditions; and it is only in the congestive form in which either Calomel or Blue Pill are wanted. But nothing affords such prompt relief in con-

gestive asthma as General Bloodletting (§ $891\frac{1}{2}$, f).

\$ 1058, x. As in epilepsy, asthma, and hysteria, so in *chorea*, the treatment is apt to be suggested by the prominent symptom, and the patient accordingly treated by antispasmodics. But they are rarely of any use, and generally injurious in these diseases, which are constantly supplying instances of the importance of addressing our remedies to the exact pathological conditions (\$ 668, 672, 673, 675, 681 c, 685, 891 $\frac{1}{2}$ b, d).

Cathartics, also, have been especially recommended by others for chorea, and so exclusively by some as to render the practice empirical. But no two successive cases are alike; one may be greatly benefited by repeated cathartics, and the next may admit of only their very moderate use, or not at all. But it is my main purpose now to express my opinion of the salutary effects of occasional doses of Calomel or Blue Pill in those cases where cathartics are indicated.

§ 1058, y. A full dose of Calomel, probably along with Jalap or Castor Oil, is generally useful in delirium tremens, as preliminary to the use of morphia; though opiates are inferior to small doses of tartarized If there be high arterial action, or much attendant disease of the abdominal organs, or any important local inflammation, Bloodletting should be premised in many of the cases. But this requires much good judgment. In a large proportion of cases this remedy is not wanted, and in many it would be seriously injurious. Where doubt exists, it should be avoided, and the main dependence placed upon the foregoing antiphlogistics, and perhaps a Blister to the nape of the neck. If Bloodletting be practised, the patient should be in a sitting posture, and its effects should be carefully observed while the blood is flowing from I bled a very athletic man, with a bounding pulse, florid skin, and furious delirium, to the extent of twelve ounces, from a large orifice, when syncope came on in an instant of time, and tumbled him from his chair. But it completely carried off the delirium, though there remained much abdominal disease to be subdued by other means, of which a dose of Calomel and Jalap was one (§ 662 c).—See Note p. 425.

In another case of a robust subject, which was complicated with intense pleurisy, I bled the patient pretty freely; but he got no relief from this or any other remedy. I advert to this instance, particularly, as simple pleurisy yields readily to an early abstraction of blood (§ 624).

§ 1058, z. In puerperal fever, Blue Pill, whatever may be the dose, is more or less useful for its local effects, and much preferable to Calomel, which is liable, in this disease, to irritate the abdominal organs injuriously (§ 1058, f). But a prompt and large abstraction of blood, as we have already abundantly seen, is the only reliable means (§ 1005, b-g).

The relative value of Calomel, Blue Pill, Tartarized Antimony, and Ipecacuanha, as gradual Alteratives in the Treatment of Inflammations and Fevers.

§ 1059. Much has been said in these Institutes of the foregoing remedies, as employed in small doses with a view to their gradually alterative effects, but mostly for the purpose of illustrating principles. They have been regarded also, with the same intention, as employed in their full cathartic or emetic doses; and it has been seen that, in whatever doses administered, they operate upon one common principle—that of altering or changing the pathological conditions. By that alterative virtue the profound action of Calomel as a cathartic, or of Tartarized Antimony, or Ipecacuanha, as an emetic, may, by a single blow, as it were, overthrow a fever, or pneumonia, or croup, &c., when the same diseases would subside only slowly under those minimum doses which may display no other remarkable effect than the substitution of healthy for morbid actions. But, however great may sometimes be the curative influences of the maximum doses, the minimum are by far the greater auxiliaries to Nature. Such is an abstract view; for, in either case, it may

be indispensable that other remedies should have prepared the way for their favorable operation, as bloodletting to secure their salutary, or to prevent their morbific, effects either as cathartics, or emetics, or gradual alteratives; or a preliminary cathartic to render useful the emetic or the slowly progressive alterative (§ 672, 867, 871, &c.).—Note Ee.

To enable us to comprehend the better how these agents quietly remove, in small and repeated doses, profound conditions of disease, it should be considered how, also, they will sometimes overcome the same by a single powerful impression—how Calomel will then display its power as a cathartic and unlock the liver,* or, at another time, calm the whole gastric and intestinal tumult of the epidemic cholera—or yet again, in the same full dose, will rouse the irritability of the stomach from apparent torpor, and set in motion the whole mechanism of vomiting-besides numerous other potent influences which Calomel is capable of exerting in its higher doses. And turning next to the agents of emetic virtues, we may trace out their unperceived operation as gradual alteratives by considering what has been said of the emetic effects of Tartarized Antimony in § 902, e-g, and by a reference to that philosophy of the operation of all these agents, through reflex action of the nervous system, as variously set forth in this work, and a glance at which may be obtained by simply referring to \$ 150, 151, 228-233\frac{3}{4}, 500, 506, 514, 516 d, No. 6, § 549-557, 841, 854, 857, 863 d, 873, 889 b, $892\frac{4}{5}$ g, 902 e-h, 904 bb.

But before leaving this subject of the modus operandi of remedies I shall employ the constitutional influences of the mercurials in farther demonstration of the doctrine which I have propounded, that remedies of positive virtues contribute to the removal of disease by substituting for the more profoundly morbid other pathological conditions that subside spontaneously, and this whether the action be exerted directly upon the part affected, or upon distant parts through alterative influences of reflex nervous action. The principle was exemplified in all its local and constitutional aspects when speaking of the modus operandi of Counter-Irritants, the Seton, &c.; but the constitutional action of the mercurials supplies another apt illustration. That effect as displayed in the salivary glands and about the tissues of the mouth is strictly inflammatory. It also subsides spontaneously. But the disease for which the mercurial had been employed, especially if acute, will have probably disappeared long before the artificial inflammation. And so of pleurisy after the application of vesicants. Now, what should be inferred from these facts? Certainly that the mercurial had altered the condition of the parts that were primarily diseased more or less according to the manner in which it had altered the condition of the salivary glands and mouth—perhaps only less intensely—only changing the already morbid states to other conditions less profoundly morbid, and thus substituting a pathological state which will subside more immediately than the transitory one instituted in the salivary glands. This, too, is farther seen in the correspondence in the increased secretion of bile in hepatic diseases as induced by the transient or more profound effects of the mercurials and the increase of saliva incident to salivation. The same principle is shown by cantharides—externally or internally. The inflammation it induces in the skin or bladder subsides quickly, but before it shall have disappeared from the surface it may have removed a pneumonia or a pleurisy; and this result demonstrates, in itself, the de-

^{*} See p. 839, § 1058 b, note.

pendence of the cure upon a reflected alterative nervous action upon the thoracic organs, which is as completely, but less intensely and transiently, morbific as when cantharides cures erysipelas by its direct application to the affected surface ($\S 854-860, 891\frac{1}{2}g$, 893 a, c-i, l, 894-901, 905). And so of the constitutional action of the unguentum hydrargyri as applied to the skin ($\S 827 e$, 904 c, 1088 b). From these analogies we pass along the gradations that are supplied by cathartics and emetics till we reach the less appreciable ones as manifested by iodine, quinine, &c. ($\S 892\frac{1}{2}c$, 893 q), and, taking along the acrids in $\S 1065 a$, we find that a common modus operandi appertains to the whole.

Tartarized Antimony.—Ranks here after Blue Pill. Others would place it as the first of the alteratives, from its almost universal adaptation to fevers and inflammations, and its great curative power. But, though far more unexceptionably applicable to these affections than the mercurials, it will not, in like manner, suddenly arrest continued fever, or acute inflammations, and, although gradually succeeding where the mercurials may fail, the latter not unfrequently have the same advantage over the Antimonial. But this comparison holds more with Calomel than with Blue Pill. Again, the mercurials exert a profound influence upon chronic inflammations, of which Tartarized Antimony is far less capable, though sometimes greatly more so, as in chronic rheumatism. The proper rank of Tartarized Antimony is probably immediately after Calomel, as gradual alteratives (§ 516 d, no. 6, 904 bb).

Ipecacuanha.—Dose, gr. ½ to gr. 1, once in four to six hours. The repetition of one grain oftener than once in four hours will, in a majority of cases, soon produce vomiting (§ 549–559, 841, 873 a). Ranks after Tartarized Antimony. Is adapted to all the inflammatory affections to which the antimonial is suited, but is much less efficient in most, though far more so in a few, as in dysentery, where Tartarized Antimony, indeed, is inadmissible. May be also employed in many irritable conditions of the alimentary canal in which the antimonial cannot. It is of comparatively little use in chronic inflammations, excepting of the lungs; and renders very little service in idiopathic fever. Its advantages in some cases of indigestion have procured for it a place among the tonics. But it has no shade of a tonic virtue, though it will sometimes bring about corresponding results by its peculiar alterative action (§ 890½, d).

JALAP.

§ 1060. In the work on Materia Medica and Therapeutics, I have given to Jalap in conformity with the results of general experience, the third rank among the cathartics. There is no other, excepting Calomel and Blue Pill, that is so powerfully alterative in inflammations and fevers, and none so safe in connection with the curative virtues which are required in the early stages of these affections, and it is an early stage of acute diseases to which I always refer. This comparative exemption from objection is rather remarkable, when it is considered that, like Scammony, the active principle resides considerably in a resinous substance, and that the resin of Jalap is an acrid cathartic. But this only shows us that we must consult the direct effects of remedial agents upon morbid conditions to ascertain their actual virtues as remedies (§ $5\frac{1}{2}$ a, 675, 686, 837 cc, 854 bb, c, 904 c). All that is of any value in this respect has been the result of experimental observation—observation limited to effects upon diseased states of the body (§ 137, d). And what

a rebuke is this to the pretensions of Organic Chemistry! Doubtless, it is greatly owing to analogical conclusions from the apparent coincidence in the resinous principles of Jalap, Scammony, &c. (§ 1063), that many have considered Jalap as unsuited to the acute stages of inflammation and fever as the other resinous cathartics. But experience shows it otherwise.

In making this discrimination, however, in favour of Jalap, it must not be entertained that it will supersede the necessity of Bloodletting in acute inflammations of important parts, and in numerous cases of fever, especially of all the congestive varieties, or that all the favourable effects of Jalap, like those of other cathartics, will not be as often promoted by previous Bloodletting in these affections; though it may be less morbific without.—See Note Ff p. 1135, as to Yellow Fever.

When acute inflammation affects the intestinal canal, neither Jalap or any other cathartic can be employed till the disease is essentially overcome by other remedies. But even in these conditions it will produce less injurious irritation than any other active cathartic, excepting Castor Oil; and it may be a good deal divested of its irritating effects

by combining with it some proportion of Tartrate of Potash.

With the exception of the Saline and Mercurial, it is the effect of most cathartics, especially of such as are called Resinous, and of Rhubarb, and Senna, to excite the general circulation during their direct operation; and this particularly if acute inflammation or febrile excitement be present. But the usual effect of Jalap is the reverse, if any present arterial excitement be not very high, and the intestine be not in a mortally irritable state. Under these circumstances, the action of the heart and bloodvessels diminishes in force and decreases in frequency during the direct action of Jalap, which, in respect to uniformity, is a remarkable property of this cathartic, though frequently witnessed of Castor Oil (§ 1057, 1).

But Jalap is recommended in the early stages of acute inflammations and fevers, with the qualification already made, not only by its comparatively unirritating effects, and its depressing influence upon the organs of circulation, but by its direct alterative effects upon diseases of all parts, under appropriate circumstances. Indeed, its alterative action is not especially manifested in any one organ; but it appears to distribute its effects more equally than any other active purgative upon all parts that may be the seat of disease. So far, it is singularly adapted to idiopathic fever, and to inflammation of all parts, excepting of the intestines. The copious secretion which it determines from the intestinal mucous membrane, and quite freely from the liver, is, also, another recommendation of this remedy in the diseases under consideration (§ 143 b, c, 148, 163, 847 g, 863 d, e, 871, 889 f, h, i, n, 900, 902 g, i).

But Jalap is rarely given uncombined. It has not, as I have said, any remarkably greater effect upon one organ remote from the alimentary canal than upon another; but by combining other remedies with it, we may not only increase its own remedial influences, but produce special effects upon particular organs. For this purpose Calomel is generally the best adjunct. The effects of this combination, when appropriate, are well known to be remarkably great, each remedy contributing to the effects of the other, extending them with greater force than either, individually, to every organ of the body, and exerting a more special sway over the liver, breaking down disease wherever it exists in a direct man-

ner, and indirectly by influences that are exerted upon organs that are not diseased, through salutary sympathetic impressions reflected, through the nervous power, from these parts (as the skin for example) upon organs that are diseased (§ 143 c, 514 k, 674 d, 676, 889 n, 902 g, m).

This knowledge of the virtues of Jalap enables us to understand how it is that the addition of a grain or two of Ipecacuanha often improves its excellent qualities, especially when Calomel is also associated in the compound. Ipecacuanha is not less remarkably universal in its influences, though determining a more special action upon the skin, and upon the lungs in their inflammatory conditions (§ 2 b, 143 c, 148–151, 855, 895, 902 f), contra-stimulant, powerfully alterative, especially when thus appointed, and tributary to the purgative effect. When, therefore, brought into union with Jalap and Calomel in the dose of a grain or two, or, if a more powerful effect as a cathartic, depressant, and alterative be wanted (§ 227), then the Ipecacuanha in the dose of five or more grains forms a compound which is truly wonderful in its curative effects, so only the remedy be suited to the exigencies of the disease.

In all that I am now saying of the uses of cathartics, or, indeed, of any remedy, the remarks must not be taken in an abstract sense, but they suppose that other remedial agents have been already employed, whenever necessary, to place the disease in a proper condition for the

remedy under consideration (§ 1058, e).

I have now stated the most useful combinations which Jalap is capable of forming with other remedies. The only other of much importance is its union with Tartrate of Potash (the bitartrate being often injurious by the excess of acid). This and Castor Oil are, in a general sense, the most useful adjuvants to Calomel, when the latter is administered in advance (§ 1057, 1).

THE SALINE CATHARTICS.

§ 1061. In the Author's Therapeutical Arrangement of Remedies Castor Oil and Aloes follow successively after Jalap, and then appear five saline cathartics in the following order: 1. Tartrate of Soda and Potash. 2. Sulphate of Magnesia. 3. Sulphate of Soda. 4. Phosphate of Soda. 5. Tartrate of Potash. This order of arrangement is intended, as throughout the whole plan, to indicate their supposed general relative usefulness. I will here remark that Podophyllum is placed as the fourth in order on account of its analogies to Jalap; but it should go down below the Juglans, as it is so fully superseded by Jalap. It yields, however, a useful extract, which Jalap does not.

The virtues of these saline cathartics are very analogous, yet each one is marked by certain peculiarities, but less individually characteristic than such as distinguish most of the other members of this family of medicines. In a general sense they are also distinguished from other cathartics, excepting Jalap, by often directly lessening any general arterial excitement which may exist at the time of their exhibition, and they have obtained, in consequence, the appellation of Antiphlogistic Cathartics. And yet their range of influence over severe forms of inflammation and fever is greatly less than that of the Mercurials, and Jalap, and Castor Oil. All these things illustrate § 500 m, 900, 902 g, h, 904 a.

But their adaptation to a vast range of mild fevers as ultimate remedies, and to inflammations of comparatively unimportant parts, gives to them the relative value which I have assigned them in the Systematic

Arrangement. But, in all inflammatory and irritable conditions of the intestines, these cathartics rarely fail of being injurious. Nor should they, as a general rule, be exhibited as a primary remedy in any disease of much importance; for, although they moderate general arterial excitement, they are but feebly alterative, and are liable, by an irritative action, to aggravate severe conditions of disease. Examples of this nature are often presented to our observation in cases where some one of these salts has been administered before summoning the attendance of a physician. These are particularly the cathartics which render much of their service by the secretion which they elicit from the intestinal mucous membrane (§ 863); but least of all do they reach the function of the liver.

It is seen, therefore, to be a peculiarity of these cathartics to irritate the intestinal mucous membrane without propagating an irritation to the general circulatory organs, even in their excited conditions, so long as they produce no injurious irritation of the intestines. On the contrary, if the disease be not intestinal, they will often greatly moderate arterial excitement during their direct operation; and it is this circumstance which has given them a factitious importance in the treatment of severe forms of disease. But the reduction of arterial action and of heat is mostly due to the free elaboration of intestinal fluids, and the absence of irritative virtues in the remedies. There is little or no alterative action exerted upon the immediate instruments of disease, where disease is at all profound. There is but little of that alterative reflected nervous influence instituted through the alimentary canal which constitutes the most valuable effect of remedial agents (§ 150-151, 163, 228, 526 a, 714, 716, 854 c, 859 b, 860, 870 a, aa, 902, 904 a). Although, therefore, the heat of the skin, and the excited state of the pulse, be moderated by the saline cathartics, it is often so only to return soon with equal or increased intensity. The remedy has not, in such cases, established salutary impressions; and, in this way, the days steal on, but each succeeding day bringing some ascendency of disease over what is gained by the illusory "cooling effects," as they are called, of the saline cathartics.

Those who depend upon their cooling effects are also apt to employ lemonade and oranges to aid in the cooling process; and, although these vegetable acids are set down in the books under the hypothetical denomination of refrigerants (§ 819, a, Mottoes), and are strongly recommended for the purpose of cooling down inflammations and fevers, it is not less certain that it is only an old relic of the humoral pathology, and that these acids have not the slightest tendency to diminish febrile or inflammatory action; but, on the contrary, they rarely fail to aggravate and prolong both. They produce an injurious irritation of the gastro-intestinal mucous membrane, thus inflicting a direct injury upon those organs through which we endeavour to convey relief to others.

Such, then, is the deceptive nature of the whole of this refrigerant system. Thousands are its victims; when one good Bloodletting, and a dose of some suitable cathartic, at the beginning, would effectually cool down the patient, and probably save the necessity of any farther active treatment in a great proportion of the cases. It is comparatively a small evil, however, with that which arises from an indiscriminate and excessive medication.

All this comes from the want of sound principles in physiology and pathology—the want of medical philosophy—and a consequent leaning upon the impracticable and visionary doctrines of the physical schools.

RHUBARB.

§ 1062. Rhubarb follows next in our Therapeutical Arrangement, and, doubtless, there are many who think it entitled to a higher rank. But, with all its reputation, its uses are comparatively circumscribed. It is not suited to any conditions of acute inflammation or fever, till, at least, they are far on the decline (§ 872, a); nor is it, at any time, a proper purgative when an active effect is required. Indeed, the real advantages of Rhubarb, as a cathartic, are limited almost to cases of diarrhoa unattended with intestinal inflammation, to indigestion, and to the stage of convalescence from most diseases, whether acute or chronic; and, I may also add, to scrofulous subjects when affected by indolent conditions of inflammation. I am speaking of it in its relations to disease as a cathartic, though it may exert simultaneously other very desirable effects. In smaller doses, other objects are in view, and they can have no participation in assigning the rank as a cathartic (§ 890, b).

Now, the reasons of this limitation are rendered obvious by considering the effects of Rhubarb upon certain diseased states of the body. When exhibited in fevers and acute inflammations, which make up the great amount of diseases, it aggravates them like stimulants and tonics; and it is also well known that it exerts the useful effects of tonics where these remedies are appropriate, as in dyspectic affections (§ 1065). Aloes, scammony, &c., increase them by irritant virtues.

Whilst, therefore, we thus learn that Rhubarb is not suited to febrile and inflammatory conditions of an active nature, the objections show us that it is well adapted to the periods of convalescence from those affections. Its mild tonic and cathartic virtues, as then manifested in small doses, give to it, under those circumstances, a high value as an auxiliary to Nature in her recuperative efforts. But in these cases, even, it should not be given uncombined (§ 872 α , 1064).

By its frequent effect in arresting diarrhoea, it is known to possess, also, what is called an astringent property. But of this I have already spoken (§ 890, b).

We have now seen that Rhubarb is cathartic, tonic, stimulant, and astringent; a combination of virtues which distinguishes it remarkably from all other cathartics. These united virtues impart to it a high value as a cathartic in certain conditions of disease, and a good substitute could not be supplied for it in those conditions. It enables us, also, to employ rhubarb most advantageously in many forms of disease where we do not desire its cathartic, but only its laxative effect that arises from small doses. In these small quantities, too, as a grain to five grains, the tonic effect of the remedy, which is then commonly desirable, is more strongly pronounced than in large doses.—Note Ee p. 1133.

On account of these numerous virtues of Rhubarb, according, in part, to the quantity administered and the nature of the disease, I have arranged it not only among the cathartics, but among the alteratives, and tonics, and astringents. For the first of these purposes it is most useful when combined with Calomel, or Calcined Magnesia, or the Tartrate of Soda and Potash, or the Sulphate of Potash; as an alterative it is often useful, in small doses, in chronic inflammations, on account of its useful effect upon the alimentary canal and liver; as a tonic in dyspeptic cases, and in convalescence from acute diseases, when its action upon the liver, and its laxative effect, are also tributary to the cure; and, as an astrin-

gent, in cases of diarrhoea unattended by intestinal inflammation, and in large or small doses according to the precise nature of the disease.

Great mischief is done by the exhibition of Rhubarb in dysentery and scarlet fever. It is employed theoretically in the treatment of the former disease, on account of the astringent as well as cathartic virtue of this remedy, while the tonic and stimulating are completely neglected, as well as its pernicious effects ($\S 892\frac{4}{5}, g$).

SCAMMONY, ALOES, COLOCYNTH, SENNA, COLCHICUM.

§ $1062\frac{1}{2}$. Three of the foregoing remedies, Scammony, Senna, and Colchicum, are produced here, not only for the purpose indicated in § $1057\frac{1}{2}$, but to exemplify the manner in which remedial agents of powerful morbific virtues are commended to an indiscriminate use in those enlightened quarters where Bloodletting is nearly or altogether proscribed, and to thus institute a farther contrast between the abuse of the Materia Medica and the neglect or denunciation of the "Remedium Principale" (§ 819 b, 891 c, 954 b, 960 a-h, 1000, 1001, 1003, 1005–1006, 1007 b).

SCAMMONY, ALOES, AND COLOCYNTH.

§ 1063, a. The cathartics following Rhubarb (§ 1062) in our Therapeutical Arrangement are, respectively, Calcined Magnesia, Carbonate of Magnesia, Colocynth, and Scammony, the last of which, therefore, occupies the 15th rank as a cathartic of general usefulness, Aloes hold-

ing the 5th, or next after Castor Oil.

Scammony is a more irritating cathartic than Aloes or Colocynth, to which it is a good deal allied in its effects upon morbid conditions, although, unlike the latter it contains a large proportion of resin, which is the active principle (§ 1060). It operates with energy upon the whole intestinal canal, and exerts an alterative reflex nervous effect upon the liver, often inducing a redundant flow of bile in the inactive conditions of that organ. It is well suited, therefore, when properly combined, to habitual and obstinate constipation, where no intestinal inflammation is It is, for like reasons, and, like Aloes and Colocynth, curative of chronic diseases of organs situated remotely from the abdominal viscera, and which owe their origin to those abdominal affections of which I am speaking, or, having a different origin, become complicated with them (§ 905, a). These three remedies, indeed, are generally adapted to like conditions; though Aloes is much the best, and Colocynth is more alterative and remedial, and less irritating than Scammony. Each is pernicious in all inflammatory and irritable states of the intestinal canal, as well as injurious in all fevers, and in all acute inflammations of important organs. Nevertheless, Scammony, like Aloes and Colocynth, is more or less adapted to mild inflammations of the mucous tissue remote from the abdomen, as in catarrhal affections (§ 904 a).

§ 1063, b. An important error prevails in regard to the action of Scammony and Aloes upon the intestinal canal, it being supposed that they exert their effects (particularly Aloes) upon the lower tract of the large intestine. This conclusion has grown out of the irritation of the anus which often attends the operation of Aloes; but it is mostly due to the morbid bile which Aloes elicits from the liver. The Mercurials and Castor Oil have often the same effect in hepatic congestions, and it often occurs when no cathartic has been exhibited. Either for this reason, or because, perhaps, Aloes contains no resin, Pereira remarks,

in his great work on the Materia Medica, that "Aloes irritates less powerfully than Jalap"! The misapprehension has led to a great extent of malpractice, particularly to the administration of this cathartic in fevers and acute inflammations, and even in morbidly irritable states of the small intestines. Aloes is, also, for the same reason, in part, withheld from pregnant women, lest its supposed action upon the rectum should give rise to abortion, a result which was denied by Denman, while, also, Aloes is an emmenagogue of some pretensions. As to the latter fact, it restores menstruation in two principal ways: 1st, by its special sympathetic action upon the mucous tissue, remote from the intestine, in its morbidly susceptible conditions, as witnessed in catarrh and gonorrhea; and, 2d, by its removal of indolent hepatic troubles and constipation, of which amenorrhea is so often merely symptomatic.

The simple fact that Aloes affects readily and powerfully the hepatic function in its morbid states should leave no doubt of its special action upon the upper portion of the intestinal canal; but, that this is truly so may be rendered evident, and Pereira's comparison of Jalap and Aloes contradicted, by the following experiment, which may be readily tried by the advocates of Aloes and Scammony, bearing in mind that, when constitutional excitement ensues, or when allayed, by the operation of cathartics, it is mostly in consequence of their action upon the

small intestine (§ 718, 889 i).

Let us, then, regard two patients, affected as nearly alike as may be with remittent fever. The skin of both is preternaturally warm, the pulse moderately full, and 100 beats in a minute. This is so far their corresponding state; the disease in its incipient stage, and there has been no treatment. Now, to one we will give 30 grains of Jalap, to the other 12 grains of Aloes; and let us take an observation of their symptoms at the time of the second alvine evacuation. The pulse of him who is purged by the Jalap has descended in frequency from 100 to 80 beats in a minute; while the Aloes has carried it up in the other to 120, being a difference of 40 beats. The skin of the former patient has become cool, and soft with an insensible perspiration. This patient is also placid, and feels himself relieved. On the contrary, the skin of the other is ardent and dry, his face flushed, his eyes wild, his head annoyed with pain, and his whole system in an agitated and harassing state. This is the test, and by this should we be governed both in practice and in theory. It illustrates also the principles in § 500 m, 863 d, 904 a, &c.

§ 1063, c. The objections which I have made to Scammony as an irritating cathartic lead me now to fulfil the purpose expressed in § 1062½, as I shall have occasion to do, also, when I come to the merits of those popular remedies, Senna and Colchicum. For this object I shall look into Pereira's elaborate and standard work upon the Materia Medica (as I have done on former occasions, § 891 c, 960 a), as one, among others quoted to the same effect, which represents the opinion of many.

"Scammony," says Pereira, "is principally valuable as a smart purgative for children, on account of the smallness of the dose necessary to produce the effect, the slight taste, and the energy, yet safety, of its operation."

I shall not speculate upon the probable consequences of this eulogium upon one of the most irritating and drastic of the purgatives that are entitled to a reputable place in the Materia Medica, nor inquire how far it may have contributed to the success of homocopathy (§ 878). But I am entitled to assert, in the first place, that such is the great liability

of Scammony to produce constitutional irritation, and excite intestinal inflammation in Children, that it should never be exhibited to them under any circumstances (\S 576 d–577); and for the ordinary purpose of

cathartics it is entirely unsuitable at any age.

Again: as to the attractive "taste" of medicines, which appears to be often of paramount consideration. Calomel, even, is recommended for Children upon this worse than mere empirical ground; and, of one of the most valuable remedies, and most appropriate for Children, I'creira says, that, "As a purgative for Children, Castor Oil has been used on account of its mildness; but its unpleasant taste is a strong objection to its use." Compare this with what he says of Tobacco at § 960, a. Neither is the "smallness" of a requisite dose to be for a moment weighed against the virtues of a better remedy.

SENNA.

§ 1064. The popularity of Senna as a domestic medicine, and the extensive use of it by the Profession, lead me to some comments which would not be otherwise made. If Bloodletting, in the treatment of inflammations and fevers, is to receive no quarter from those who build their hopes upon a more popular practice, or lose sight of pathology in the novelties and promises of Organic Chemistry, let us see to it that they do not escape without rebuke for their lavish use of the violent articles of the Materia Medica (§ 819, b).—Note H p. 1117.

Pereira, in his able work upon the Materia Medica, supplies the best authority as to the general estimation in which Senna is held. "Taken by the stomach," he says, "Senna acts as a sure and safe purgative;" and again he repeats, "It is a very safe purgative, and may be given to

Children, Females, and Elderly persons with great security."

That Senna is a "sure purgative" is as true as the same affirmation by our Author of Scammony (§ 1063, c); but it is nearly as far as Scammony from being entitled to the same general commendation of being "very safe." On the contrary, in my judgment, there is no other cathartic, in the hands of Physicians, which has been more extensively injurious than Senna; and this being so, I shall indicate its bad qualities

before speaking of its good.

In the first place, Senna is rarely capable of any very salutary effect upon inflammations, either acute or chronic, or upon fevers. By its irritative virtue, it excites the general circulation; and as it is profoundly irritating to the whole mucous tract of the bowels, it rarely fails to aggravate idiopathic fever, or to exert injurious reflex nervous influences upon any inflamed organs. We have already seen how Rhubarb is misapplied in this manner, especially in dysentery (§ 1062). But that remedy inflicts its injuries in active forms of inflammation and fever by its tonic and stimulating properties—Senna, by its irritating (§ 889, a). And here, by the way, it is apropos of the Author to whom we are now paying our respects, that he says of Rhubarb that, "Given at the commencement of disease, it is a very popular remedy; and though doubtless it is often employed unnecessarily, it rarely if ever does harm." True, he also says that "it is not fitted for inflammatory or febrile cases."

But, as to this Senna, it may be safely said, that it should never be employed but with a simple view to its purgative effect, and then only in constipated states of the bowels when unattended with any inflammation of those organs. The griping of Senna is proverbial; and Physicians

have vainly flattered themselves that this effect may be counteracted by uniting Manna, or the Saline Cathartics, or a purgative Tincture, or some carminative, like Coriander or Anise, with an infusion of Senna; nor does a moderated heat in its preparation lessen the evil. What, then, does that griping imply, considering its universality? Certainly, an excessive irritation of the intestinal mucous membrane, and such, too, as is very likely to result in disease of the intestines, if these organs be in a morbidly irritable state. If any disposition to inflammation be present in any one of the tissues of the intestines, the action of Senna will be very likely to develop an attack of that disease. If any venous congestion affect the liver, it will be aggravated by the irritating properties of Senna. And, as it regards inflammations of other parts, and idiopathic fever, it is very likely, as is known in the best experience, to send its morbific influences abroad from the abdominal organs over those Among the worst and most common manifestations of this affections. are the sad effects of Senna in the treatment of scarlet fever.

The objections to Senna grow out of its radical fault of possessing very little alterative virtue of a useful nature, and a great deal of a morbific (§ 854, d). But a difference in this respect obtains in different climates; which applies, also, more or less, to other irritating cathartics, and to Tartarized Antimony in *emetic* doses. In latitudes north of about 40° these remedies are better borne than in the more southern; the reason of which is, that in New York and South there either exist in most complaints, or there is a great tendency to, derangements of the abdominal viscera.

Having, therefore, so little to say in commendation of this notorious member of the Materia Medica, and having dwelt sufficiently long upon its demerits, it only remains to be added, that it is most salutary when it takes along some one of the meritorious neutral salts.

COLCHICUM.

§ 1065, a. The most obvious effect of Colchicum, in small and repeated doses, is that of irritating the intestinal mucous membrane, as evinced by a purgative effect. In larger doses it produces nausea, vomiting, and hyper-catharsis. Indeed, this remedy is commonly arranged with the cathartics, though it is rarely employed with the usual intentions of a purgative. I am quite satisfied, however, that it will not often afford much relief in gout or rheumatism (to which its uses are mostly restricted) till it produces some purgative or laxative effect. For this reason, particularly, I have given it a low rank among the Cathartics in the Therapeutical Arrangement of the Materia Medica. This effect, indeed, is what we are to carefully watch; since, when it begins, if the dose have been large, or the intestines unusually susceptible, the purging is liable to be excessive and injurious.

Various incidental results are stated by Authors as following the use of Colchicum, such as occasional sweating, occasional increase of the flow of urine, &c. But these are only contingencies to which almost all remedies may lead, under particular circumstances of disease, and are of very little importance in an abstract sense (§ $422 \ b$, $863 \ d$, e, $892 \frac{3}{4}$). It is worthy of remark, however, that Colchicum often reduces the frequency of the pulse, though at other times it exerts an opposite effect. But the interesting fact relates to the diminished frequency, which has been taken hypothetically as a ground for the administration of Colchicum as a

remedy for all kinds of inflammation, and is one of the expedients that have been devised for getting rid of Bloodletting. This brings me to one of the objects set forth in \$1062\frac{1}{2}.

"Mr. Haden," says Pereira, "was the first to direct attention to the advantages to be taken of this effect in the treatment of inflammatory diseases (ut

cit., § 1063, c).—Nоте I р. 1118.

I know not to what extent this very limited view in Therapeutics may have prevailed; but it has been, probably, the occasion of an effort now making in the United States to substitute for Bloodletting that very violent agent the Veratrum Viride, which has been long known to lessen the frequency of the pulse by an acrid narcotic virtue which it possesses, and which belongs to some of the acrid cathartics. The whole of this practice appears to have been suggested by a similar error in respect to Digitalis, and by the attempts that have been made to substitute Tobacco and Aconite for Loss of Blood (\$500 m, 826 cc, 893), 960 a).

Neither Colchicum nor Veratrum exert any antiphlogistic effect excepting upon those specific forms of inflammation which constitute rheumatism and gout; and both of them will aggravate these diseases in their acute condition till they are effectually moderated by Bloodletting, Tartarized Antimony, or other direct Antiphlogistics. In that respect they are upon common ground with quinine in its relation to intermittent inflammation, and with iodine to the scrofulous. They are very remarkable exceptions to all the general antiphlogistic means which are alike adapted to the early stages of the specific and common forms of inflammation, and which are indispensable at that stage, as preliminary remedies, to the favorable action of the specific ones upon the special. modifications of inflammation to which they are alone adapted (§ 662, $671, 892 m, p, 892\frac{1}{2} c, e, u$). More remarkable exceptions occur in guaiacum and other substances of allied virtues which are peculiarly suited to chronic rheumatism, while they aggravate any other form of inflammation. Nor is it an uninteresting fact, that all these things, Colchicum, Guaiacum, Veratrum, Asagræa, Delphinium, Xanthoxyllum, Aconite, Mezereon, Savin, are acrids (§ 892 b, 892 v, 904 a).

 \S 1065, b. These, however, are only strongly pronounced characteristics; for the critical observer will find the same distinctions prevailing in various degrees throughout the Materia Medica, and they show us that experience, and not theory, is, or should be, at the foundation of all our knowledge of the virtues of remedies (\S 2, c); and not only so, but that we can have no just apprehension of their relations to disease without a long series of trials in the endless variety of pathological conditions, their fluctuations, their localities and sympathetic influences, or as they may involve the universal body, according to the range of inquiry which pervades these Institutes; and when the student shall have examined its details and principles, and seeing that there is not a conflicting fact or induction, but that it is a perfectly consistent and harmonious whole (\S 1, a), let him interrogate himself as to whether he can summon a fact or a doctrine from Organic Chemistry that will disturb that relationship, or withstand its united force.

§ 1065, c. But, however this may be, so long as the Chemical doctrines are in the ascendant, we may not hope that experiments of the foregoing nature will cease to occupy the place of rational Medicine. Nay more; failing in these, and considering the unpopularity of antiphlogistic remedies and the acceptable nature of the invigorating, we

need not be surprised that the Chemical treatment of disease is so extensively governed by the Brunonian philosophy. Of that philosophy I have said something in these Institutes, and adduced an example of its prevalence in the British Army when Robert Jackson undertook to demonstrate its real merits ($\S 621a$, $890\frac{1}{2}f$, 960a, p.717, $\S 569e$, 1006f, 1068). But how little would this Reformer rely upon human efforts could he now read the brief paragraph which follows:

"Costly Medicine.—A London (Eng.) paper says: 'The consumption of wines in our public hospitals constitutes one of the heaviest items of their expenditure. The wine account at Guy's Hospital last year, £1083; the spirit account, £376—total, £1459 (\$7295). At St. Thomas's, the wine account was £629; spirit account, £521—total, £1150; or £2609 (\$13,045) in one year in the (two) borough hospitals alone.' "—Boston Med. and Surg. Journal, July 2, 1857, p. 448.—Note F p. 1114.

§ 1065, d. Again, as to Colchicum. This is also one of the many violent remedies that have been employed not only as a substitute for Bloodletting, but commended in doses at which Bloodletting revolts

(§ 960, a, p. 717). Thus:

"In some experiments," says Pereira, ut cit. (made with Colchicum on a healthy individual by Dr. Lewins), "debility, a feeling of illness, and headache were experienced. This feeling of debility is not, however, to be referred to the evacuations produced, for, as Dr. Barlow has observed, the number of motions is sometimes considerable without any proportionate diminution of strength. I have known, says Dr. Barlow, even twenty stools occasioned by a single dose of Colchicum, the patient not complaining of the least debility."—Note G p. 1116. Also, p. 656.

Now here is something of which we have a right to complain. In the first place, that Dr. Barlow should isolate a case of this nature, and put it forth to show that we have nothing to fear from "twenty stools" by a single dose of this most violent substance; and, secondly, that Pereira should quote it for the same purpose, and in opposition, even, to

Dr. Lewin's experiment upon a healthy individual.

Having done this mischief, Pereira ultimately relates instances of death from over-doses of this medicine, and remarks that, "in poisonous doses, Colchicum acts as a powerful poison." Now, to my apprehension, when "a single dose" of any "powerful poison" produces "twenty stools," it is verging very closely upon its poisonous effects; and whenever Colchicum may treat our patients in that reckless manner, we may fear, at least, some troublesome intestinal inflammation as a consequence. There never was, and never will be a patient purged twenty times by "a single dose" of any cathartic, without being the worse for the violence inflicted upon his intestines (§ 960, a, p. 717). There can be no topic more worthy of professional criticism.

But I have been actuated in this disquisition only by a sense of the importance of considering well how the violent agents of the Materia Medica are often commended to our rash and indiscriminate use; and in so doing, to show, also, how probable it is that the same inconsiderate view of the subject has led to protestations against the most important of all remedies in the treatment of inflammations.—Note Hp.1117.

§ 1065, e. There can be no doubt that Colchicum manifests a much greater control over gout than rheumatism; and, although this is generally conceded, all practitioners do not agree as to the extent of its influence. Some of the most able and accurate observers, such as Sir E.

Home, and Dr. Paris, pronounce it a specific for the disease; while others, like Sir C. Scudamore, consider it, at best, only a palliative. Indeed, Scudamore, in his treatise on the gout, is disposed to look upon Colchicum with great suspicion, believing that, although it be a present means of relief, it increases the tendency to a repetition of the paroxysms. He thinks, also, that it loses its remedial effects by frequent use, although considerable intervals intervene between the attacks. Very much, however, will depend upon the particular circumstances of the case when the remedy is exhibited. If given at the onset of acute gout without antecedent Bloodletting, or when the abdominal organs are in a morbid state, we may look for disappointment.

ON THE ACTION OF CHLOROFORM, AND ANALOGOUS AGENTS IN PRODUCING INSENSIBILITY WHEN INHALED.**

§ 1066, a. The general prevalence of the Chemical or other physical doctrines of life, and the consequent interpretation of Pathology and Therapeutics upon the same principles, has necessarily led to as extensive a revival of Humoralism, and, as one of its dicta, that the causes of disease, and the curative means, so far as the nature of things will admit, are absorbed into the circulating mass of blood, where they effect their results in the blood or the solids through some chemical process (§ 40-46, 350, $350\frac{1}{2}-350\frac{3}{4}$, 821 c, 828 d, 830, 837 a, 840, 893 e, 904 b, 905 a, 1034). All but Setons, Cold, Mental Emotions, &c., are carried to this account (see Indexes); and even some of the soundest Physiologists in other respects maintain that the poison of the Viper, Hydrocyanic Acid, and the spirituous extract of Nux Vomica are absorbed when the last two destroy life in a second of time, notwithstanding, also, it is palpable that their fatal action must begin on the instant of their contact with the lungs or the mouth (§ $350\frac{1}{2}$ p, 441 f, 487 g, h, 494, 826, 827, 828 α -e, 829, 904 b, &c.).

And so, to question the assumption that chloroform and analogous agents produce their effects only after being combined with the circulating mass of blood, according to Liebig's or some kindred hypothesis (§ $350\frac{1}{2}$, n, p), is held to be an evidence of ignorance in Physiology, and unworthy a moment's consideration. But, before this doctrine can be sustained, the facts in the foregoing references, and a multitude of others contained in this Volume, must be disproved. True, the blood is said to be changed in its colour, but that would necessarily arise not only from the exclusion of atmospheric air, but from the morbific action of the anæsthetic through the ordinary laws of sympathy, and is upon the same ground as the supposed absorption of Carbonic Acid Gas (§ 419, 827 b). Again: some may have supposed that they have smelt those agents in the blood (§ 282). But the sense of smell is apt to be fallacious, especially when in pursuit of some particular odour or some favourite hypothesis, and it is difficult to contradict it. But this would prove nothing as to their mode of operating; since, especially, others have failed of detecting the odour of the most fragrant and fatal (§ 494, 827 d, 904) b, c). Moreover, the odour of chloroform and of sulphuric ether is very diffusive and impressive, so that if even a minute quantity of either substance entered the circulation, it should be detected without the aid of the imagination. A drop of ether will impregnate the air of a large room. We have had reports of alcohol having been thus observed, and they have been appropriated by the Chemist accordingly (§ 440 bb, No.

^{*} I will not forego this opportunity of expressing my full conviction that the honor of this discovery, and of its first practical application, belongs to Dr. Horace Wells.

9, § 441 c, 1048–1049); nay more, of the blood burning like a flaming current as it issued from a vein, and even of the spontaneous combustion of inebriates.* (See all the reported cases in *Med. and Physiolog. Comm.*, vol. i., p. 576–581, where each one is shown to be without foundation.) But alcohol is not absorbed (LIEBIG, p. 172, § 350, no. 94).

The veins of different organs have been, also, found congested after respiring the Anæsthetics, but less frequently of the brain than of some other parts. But this, too, proves nothing of absorption; for the same is the case when Hydrocyanic Acid, and the spirituous extract of Nux Vomica, whether taken by the stomach, or applied to the mucous membrane of the eyes, or nose, or mouth of rabbits, destroy life in a second of time (p. 675, § 904 b, 494 dd, 826 d), or the virus of a snake in a minute (§ 828 c). And let these observations be taken in connection with Girtanner's experiments and those of others (§ 494 b-dd), and with the remarkable results from pricking the floor of the fourth cerebral ventricle (§ 1032 d) and with the respiration of ammonia, &c. (§ 827 c).

But the question is not whether Anæsthetics or Nitrous Oxide be absorbed, as very possibly they are more or less, but whether they produce their effects through the medium of the blood, or by reflex actions of the nervous system. (See § 284, 1088 d. This distinction is fully con-

sidered in various places. See Index II.)

As the whole of this ground, however, has been gone over extensively in these Institutes, it is mostly the purpose of the present Article to bring the question under the trial of facts embraced in the foregoing sections, and others to which they refer, along with our demonstrations of the nervous power and its laws of reflex action; though the subject might have been left to a single consideration, which appears to me to be conclusive against the doctrine of operation by absorption, and which I shall

now address to the Physiologist.

§ 1066, b. In the first place, then, it is conceded that the blood is from one to two minutes, at least, in going the round of the circulation (§ 904, b). It should, therefore, occupy nearly that time after the respiration of the Anæsthetics is begun before insensibility takes place, which is equally true, also, of Hydrocyanic Acid and the extract of Nux Vomica (the latter of which is not volatile, § 494 dd, 826 d), which have been known to destroy animals in a second of time (§ 904, b). But this is not the specific fact to which I have adverted, though it should be taken in connection.

I say, then, if insensibility depend upon the absorption of the Anæsthetic agents there should be no necessity for their unceasing respiration, or quick repetition, to maintain their effects. The blood once charged, or however modified, should be capable of prolonging insensibility far beyond any thing that is observed in experience. But if, on the contrary, the effect arise from the influence of the agent upon the pulmonary mucous membrane, and be thence propagated by the nervous system, it would be quite likely to subside soon after atmospheric air is freely admitted to the lungs, as in § 481, α -h. Precisely the same peculiarities attend the respiration of the nitrous oxide gas (§ 827, c). The subject is quickly brought under its power, and his faculties are often fully restored in less than half a minute after atmospheric air is substituted. This is as true of Amylene as of chloroform and sulphuric ether. Thus, Dr. Orton, of Binghamton, N. Y., on administering siij. of amylene, produced "complete insensibility in about two minutes." "Just as I was

* It has been lately reaffirmed by French chemists that alcohol, chloroform, &c., occur within the body, after their ordinary use, in a free state. See § 350, nos. 43, 94.—1861.

about to perform the surgical operation intended, the flexible tube with mouth-piece separated from the inhaler, and before I could adjust it my patient had completely recovered her usual sensation." The inhalation was repeated, and "the larger nail torn from the toe without the slightest uneasiness."* (New York Journal of Med., Sept., 1857, p. 286.) Now, will any one believe, with his logical powers awake, that such a sudden transition, in either of the cases, could possibly happen were the phenomena owing to an incorporation of these substances with the circulating mass of blood! Give to the Chemical, or any other physical hypothesis, the greatest possible latitude of construction, or expound the results upon the vital theory, it is plain that when these agents are once circulating in the labyrinth of the organism, and in sufficient quantity to produce the astonishing momentary effects, they would continue to do so, in gradually diminishing degrees, until ample time should have elapsed for, at least, their elimination by the emunctories.

Again: the doctrine of absorption is contradicted by the necessity of diluting the anæsthetics with atmospheric air to prevent immediate death, which may happen so quickly as to preclude the hypothesis. This necessity of dilution supposes, therefore, the action of the Anæsthetics upon the nervous system of the lungs, and their transmitted influence over the entire organism by the reflex action of the nervous power; and this is farther seen in the fact that a greater amount would be absorbed during a long-continued respiration of the diluted agents than could happen when only momentarily exhibited in a concentrated state, and therefore death should as certainly follow in the former case. Moreover, all the earliest phenomena denote the direct action of the agents upon the lungs. Why are the effects so different when taken by the stomach?

The whole philosophy, therefore, is perfectly explicable through what is known of the different susceptibilities of the various tissues, and in their various parts to the action of external and internal causes, and the wonderful attributes of the nervous system; and which enable us to comprehend the reason why the Anæsthetics so rarely affect the organs of organic life (§ $233\frac{3}{4}$, 422, 425 d, no. 7, 481 a-h, 487 h, 500 g, m, $891\frac{1}{2}$ g, k, 893\frac{1}{2}, 1088 c, and Indexes, Art. Structure, Nervous Power).

By the same philosophy we as readily comprehend the reason why the respiration of the fumes of Hyosciamus and of Opium establishes profound effects upon the whole organism, when no such result arises from smoking tobacco (§ 904 b). But what is very exact and comprehensive is the effect of ammonia when respired as a counter-poison for hydrocyanic acid. Here can be no relief from absorption, for hydrocyanate of ammonia is an active poison,

* I have introduced this case for the purpose, particularly, of referring to the remarkable fact that "the eyes of the patient were not closed at any time during the operation, but she seemed to amuse herself with an examination of the apparatus. She answered questions put to her with considerable promptness, and, in fact, conversed with my assistant during the period of insensibility," nor "was she aware that the nail had been removed when she recovered her sensibility. The pulse was but slightly accelerated."

There is no contradiction between this statement and that "complete insensibility" was effected. The latter refers to common sensibility, the source of pain; and the experiment illustrates admirably the distinction between common and specific sensibility (§ 197-201). The experiment, in thus showing the limitation of the anaesthetic influence to the nerves of common sensation, and in leaving the mind unaffected, as, also, the action of the heart, goes with our other facts in disproving operation by absorption.

The analysis which the experiment has supplied as to the modification of sensibility may be carried analogically to the organic properties, and be thus employed in corroborating our analysis of those properties (§ 170 a, 172, 175 a, b, 183-193, 205-221).

† That death is owing, as surmised by some, to the exclusion of atmospheric air, is contradicted by the phenomena, and by the failure of restoratives (§ 634).—See Note M p. 1120.

M p. 1120.

THE INFLUENCE OF THE MIND UPON THE ACTION OF REMEDIAL AGENTS.

§ 1067, a. Much has been said in this work upon the influence of the Mind in the production and cure of diseases; and it is now my purpose to extend this inquiry, very briefly, to the influences of the mind upon the action of physical agents, both as predisposing the body to the action of foreign morbific causes, and as modifying the operation of remedies. It will thus form an Appendix to what is said of the "General Philosophy of the Modus Operandi of Remedial Agents," or, rather, a grouping of many relative observations that are disseminated through the Institutes. (See INDEXES, Articles Remedial Action, Remedies, Mental Emotions, Mind, and Will.) The subject is practically important, and goes far in denoting the laws which govern the operation of physical agents upon the body, and in drawing a broad line of distinction between Chemistry and Physiology.

I say practically important; for who, indeed, of the Medical Profession has not suffered the experience of seeing the useful effects of remedies defeated by the despondency of his patient, or by some saddening emotion awakened by the indiscretion of friends, and often by a brief attention to business engagements, or by far simpler occupations of the mind? But there is great variety in these respects, according to the pathological conditions and the mental influences. The differences in results coincide, also, with such as are witnessed of physical agents; the same philosophy interprets the operation of both; and the same careful

regulation of one is often as important as that of the other.

It is a matter of daily observation, in acute diseases, that the casual visits of relatives and friends, however much enjoyed by the sick, leave them for the worse; an effect entirely the reverse of what is witnessed of the same excitements in chronic forms of disease. But this corresponds with what is seen of the difference in the results of bodily exercise and tonics and stimulants in acute and chronic maladies. On the other hand, however, the subject of acute disease may be essentially benefited by the subdued cheerfulness of an habitual attendant. He may be, in like manner, seriously disturbed by listening to a page from a Romance, when, on the contrary, he would derive an advantage from an appropriate Chapter of the Bible; and yet both of these are remedial in chronic diseases. Nevertheless, there is a perfect consistency in the philosophy which attends the effects of those causes in the two cases whether Nature be embarrassed by mental troubles and pleasurable excitements, or aided by placid cheerfulness and buoyant hope. The moody dyspeptic is invigorated in his digestion by every kind and degree of mental enjoyment, and his laxative and tonic medicines are sure to serve him best when his constipating melancholy is occasionally broken by hilarity of mind; while the subject of fever, though lacerated by exhilarating emotions, is started along by every smile of his Medical Attendant, and every remedy yields a boon to Nature under the influence of that smile, when a solemn countenance may make all the odds between recovery and death. In acute diseases, it is the tranquil emotions that do the service, while all of a joyful nature are scarcely less embarrassing to art than they are instrumental in the cure of chronic maladies. So nicely graduated is this principle in its operation, that it often happens that the subject of fever will make greater improvement in the hands of a common nurse than in those of a sympathizing friend. And yet there never

fell from the lips of the Medical Attendant a word of encouraging pity that did not tell favourably on his Castor Oil or his Narcotic.

It is, of course, impossible to analyze the precise influences of the mind upon the action of remedies in mitigating or aggravating disease. principle is abundantly pronounced in morbific effects of the mind, that are independent of other causes, in embarrassing the favourable action of remedies; and it not unfrequently happens that the mental condition may baffle the best efforts of art, not only as a fundamental evil, but as crippling the curative means; while, on the other hand, when the same mental trouble is supplanted by happier thoughts, its baneful consequences not only yield as a spontaneous effect, but are hastened in their decline by the new mental influences. From these premises we may reason to all the transient and infinitely diversified affections of the mind that spring up in the progress of diseases which have their origin in physical causes alone, and calculate, with much exactness, the effect of one passion or another in aggravating or moderating disease, and how far they may embarrass or facilitate, through those modifying influences, the effects of remedial agents. But, to carry this analysis into practical effect in the treatment of acute diseases, there must be the same reference to their nature and fluctuations that is demanded for the right application of the Materia Medica, though it may be comparatively unimportant ($\sqrt{167}$ f, note, 476 c, $476\frac{1}{2}$, 500 k-p, 509, $891\frac{1}{2}$ k, $892\frac{3}{4}$ b, 951 c)

We have variously seen how the susceptibilities of organs to the action of physical agents are increased by morbid states, and it is exactly the same with mental emotions as with the physical causes; and with what prodigious power, especially in acute diseases, the latter may operate, can be readily inferred by considering how, in healthy states of the body, one passion, as fear, will agitate the voluntary muscles, depress the circulation, but impart a bounding motion to the heart, give rise to vomiting, open the floodgate of the kidneys, expel the contents of the bladder, protrude the eyeballs, drive the blood from the face, and bathe the skin with perspiration; or, how anger braces up the voluntary muscles, rouses a vehement circulation, &c.; or, how shame strikes at the capillaries of the face and injects them with blood; or, how marvellously love plays with its shafts; or, how hope ever gladdens the heart; or,

how joy and anger may be instantly fatal.

So far, therefore, as the mind can have a bearing upon the action of remedies, it is by its direct influences upon the pathological states, through which it renders them more susceptible of either salutary or morbific impressions from physical agents, or renders them inoperative; while, also, it co-operates simultaneously, as an independent means of cure, or proves a direct morbific cause ($\frac{1}{2}$ 233 $\frac{4}{5}$, 500 k, 647 $\frac{1}{2}$, 903).

If the inquiry be extended to many of the familiar phenomena of the organic life of man, it will be seen that the mind is more or less interested in all the healthy functions; and it goes to supply more delicate illustrations of the influence of the spiritual part upon morbid states of the body. This, for example, is habitually seen in the improved appetite and more vigorous digestion, on occasions of festivity. Nor is it alone the unflinching manner in which the stomach meets its unwonted task (and much to the admiring wonder of the chemical philosopher), but it yearns for the multitudinous variety as the odour regales the nose, or the clattering of dishes delights the ear, and under the influence of which the mouth overflows with saliva. And now, if we reverse the

case, and suppose the Party, as soon as completing the repast, to be thrown into a paroxysm of fear of a few hours' duration by some impending catastrophe, it is certain that digestion would have made but little or no progress. Observe, again, how some remedies of active virtues are more or less governed in their effect upon comparatively healthy individuals by the varying conditions of the mind, as seen in the suspended or defeated operation of cathartics by any close attention to the daily affairs of life, and how, on the other hand, their effect is promoted by giving the attention to the anticipated results (§ 500 e, nn, 902 l).

§ 1067, aa. A well-marked example will illustrate the complex influences of physical agents and of the will and mental emotions when in simultaneous operation. Thus, when the voluntary muscles are slightly affected by nux vomica an aggravation of the spasm is often produced by any sudden alarm. A lady to whom I had administered a few very small doses of strychnia suffered some twitchings in the muscles of the legs when she walked in a careless manner, but was able to govern her limbs steadily by a careful effort of the will. In this condition she walked into Broadway, when, on being a little jolted by an uneven stone, she began to stagger, and, struck with alarm lest she should be considered intoxicated, she fell upon the pavement. This is not an uncommon example; and now for the rationale. That the spasmodic effects of nux vomica are owing to influences transmitted by the organic nerves of the gastro-mucous tissue to the cerebro-spinal axis, and a consequent development of the nervous influence and its reflection upon the voluntary muscles through cerebro-spinal nerves, needs no farther demonstration. The will was capable of surmounting that development by its own forcible excitation of the nervous power that gives rise to voluntary motion (§ 893); but the sudden alarm not only arrested the operation of the will and allowed the tetanicits unrestrained action, but the alarm generated an exciting nervous influence which concurred powerfully with that of the physical cause. The philosophy as to the will is the same as when conia counteracts the spasmodic influence of strychnia, or as when coffee increases it (§ $891\frac{1}{2}$ g, k, 984 b, note), only, in the case of the mind the excitation of the nervous influence is direct, in that of physical causes reflex. And so of the will and sea-sickness (\$ 113–117, $222-233\frac{3}{4}$, 245, 266, 476 e, 500 c, $638\frac{1}{2}$, $647\frac{1}{2}$, 893, $893\frac{1}{2}$, 1077).

§ 1067, b. Upon what principles, then, are we to interpret all the variety of effects which the different mental emotions display in the organic life of man? Simply, as already explained, by their operation through the medium of the nervous power, and the modifications which they bestow upon that power according to the nature of each passion. There is thus, throughout, a perfect coincidence between the operation of the mental and physical causes, since, whenever the latter give rise to effects beyond the direct seat of their operation, and thus bring the nervous power into action (§ 1039–1041, and references there), their resulting influences will, as in the case of the passions, depend upon their precise nature, and the special manner in which they modify the nervous power, as set forth in the foregoing sections (§ 227–232, 500 k-p, 503–505, 647½, 649 b, c, 657, 892 b, 893¾, 893 e, 894 b, 902 g-l).

§ 1067, c. From what has been now said of the coincidences between the effects of the mental emotions and remedial and morbific agents, and that they all operate upon a common principle (§ 854 c-857, 859 b-860, 894-905), and as the former are in perpetual operation, either for good

or for evil, it becomes evident that the Practitioner may be as intelligibly and as much interested in regulating the mental as the physical treatment of disease. The latter generally preponderates, often greatly, in importance; but occasions are constantly arising in which the former should take the lead, while it has at all times the advantage of being converted to the salutary effects of physical remedies.

Would our limits admit, we could draw upon the histories of lunacy for a vast amount of materials to illustrate the philosophy and practical importance of our subject. But all this will readily suggest itself to those who may study the phenomena of insanity in connection with the

philosophy of the mind in its relations to organic life.

§ 1067, d. What we have now and hitherto seen of the precise correspondence between the effects of the passions and of physical agents in the organic life of man may be carried with the effect of the clearest demonstration in proof of the substantive, self-acting nature of the Soul (§ 1069-1077). This must be conceded by Philosophers of every school; and those who agree with the present writer in his construction of the operation of the nervous power will see how greatly the demonstration is extended by regarding that power as the medium through which physical agents exert their effects upon parts remote from the direct seat of their operation. Here we have a common exciting cause for the common phenomena. The mental emotions, in one case, bring the nervous power into action by their direct influence upon the great nervous centre, while physical causes, in the cases supposed, develop the power indirectly, and in all the cases each agent modifies the power according to its own special nature, and directs it in so complicated a manner, and according to an incalculable amount of contingent circumstances, through a labyrinth of nerves, as to form the most difficult problem in Physiology (§ $233\frac{3}{4}$, $475\frac{1}{2}$, 500 c-p, $647\frac{1}{2}$, 894, 902 l).

But to the mere practical man, who aspires beyond the walks of empiricism, the effect of the passions in the production and cure of disease, and their undeniable operation through the nervous power, supply a ready apprehension of those analogous problems which attend the operation of morbific and remedial agents of a physical nature, and a fruitful

means for contesting with the Chemist the field of Physiology.

HAVE DISEASES UNDERGONE CHANGES OF TYPE WITHIN THE LAST FORTY YEARS, OR HAVE NEW ONES APPEARED?

§ 1068, a. By change of type I mean that radical change which is supposed to justify the substitution of the stimulating for the antiphlogistic treatment of inflammatory and febrile diseases. In this acceptation I answer the interrogatory as it has been in all past time by every truly enlightened and impartial observer. John Brown, the great Antagonist of Nature, and who leads a host in his train, is in no respect an exception; for, whatever may have been his genius, he had very little practical knowledge, was intemperate in his habits, and the revolution which he achieved was prompted by animosity towards Cullen and other early friends. As it is important to understand the ground upon which this School originally stood, I shall introduce a brief sketch of its origin from the "American Encyclopædia." Thus:

"Brown was admitted, as an indigent scholar, to a gratuitous attendance on the lectures (Edinburgh), and obtained the patronage of Dr. Cullen, who employed him as a tutor in his own family. During this course

of study, he married, and set up a boarding-house, but failed, and became bankrupt. About this time, by a long course of meditation on the animal system, and the vigour of his own mind, directed by some reading, but seconded by little or no aid from practical observation, he elaborated a new theory of medicine. The result was, the publication of his Elementa Medicina, which he farther explained in a course of private lectures. Brown scrupled at no means to push his doctrines. A new medical language was introduced; ideas totally at variance with former opinions were maintained; and the most virulent abuse of the regular Professors of the University was perseveringly uttered. At length, ruined in reputation, he repaired, in 1786, to London. Here he endeavoured to excite attention by his Observations on the Old Systems of Physic, but without success."—The day of success, however, was not long delayed. The Elements of Medicine had the advantage of being written in Latin; and as the simplicity of its doctrines, and the practice inculcated, were novel and fascinating, all Europe soon became ensuared by the charm ($\$621\ a$, $890\frac{1}{2}\ f$, $960\ a$, p. 717, 719, $\$1006\ f$, $1065\ c$).

§ 1068, b. Under my own observation there has been no change in the character of diseases, with the simple exception that some forms have been less unyielding within the last twenty years than during the preceding twenty. But this qualification is mostly limited to the common forms of local venous congestions and congestive fevers (§ 757-785, 786-818, 961-970). These affections have yielded, during the latter period, to rather smaller abstractions of blood, and smaller doses of medicine, particularly cathartics. But precisely the same general mode of treatment has been indispensable to an early recovery, or to a complete removal of the disease, or to the preservation of life; while, on the contrary, the prevailing Brunonian treatment has been distinguished by its former disastrous effects (§ 1068, a). In proof of this, I need only advert to the excessive mortality which has attended the yellow fever within a few late years, and in the treatment of which the stimulating plan has been generally practised (INDEXES, article Loss of Blood). As an example of the mortality, under the stimulating method, it is stated in the able Report of a Committee of six Physicians on the "Yellow Fever at Norfolk, Virginia, in 1855," that

"The number of deaths was about 2000, or one fourth of the entire population remaining in the city. When we consider that half of this population was black, among whom there were few deaths, it seems probable that more than one third of all the whites attacked, died."-Report, &c., p. 38; Richmond, Virginia, 1857.*—Notes F, Ff, Gg, II.

^{**} In the same Report it is stated that the yellow fever "in its symptoms was much the same as all the great epidemics that have occurred either here or elsewhere" (p. 38). It was early in this epidemic that some physicians entertained the hope that the *Muriated Tincture of Iron would prove a *specific for the disease.

Here, also, we meet, among other important statements, with an observation of crushing weight to the doctrine of contagiousness of yellow fever. Thus:

"In no case that we have known or heard of was there the least reason to suspect that the disease was contagious. *Many lundreds of our people, flying from the pestilence, sickened and died in the neighboring counties and cities, in hotels and private houses, in infirmaries and hospitals, under all possible varieties of place and circumstance, and yet we have not heard of a *single instance* in which it was ever alleged that the disease was communicated to the attendants or friends" (p. 38).

The foregoing appeared in the fourth edition of this work, and it is pleasant to incorporate in this sixth edition the following resolution, passed by the "American Quarantine and Sanitary Convention," at its fourth annual session, held June, 1860:

"Resolved, That the action of the last Convention on the question of the non-contagiousness of yellow fever, to be found on page 45 of its Transactions, be and is hereby reaffirmed"—a question to have been settled upon the philosophical grounds embraced

As to the acute and chronic forms of inflammation, I have observed still less of the modifying effects of remote causes (\$ 644–676, 710–756). In the acute form, as affecting all great organs, the same amount of bloodletting, the same cathartics, though in smaller doses, the same alterative antimonial treatment, &c., have been either necessary to life, or to an early and perfect recovery. In all these respects, pneumonia, pleurisy, inflammation of the brain, peritoneal inflammation of the intestines, puerperal peritonitis, rheumatism, &c., have remained without modification, or with the exception only that Cathartics require a more careful regulation of their doses (\$ 857, &c.). In these conclusions I am also sustained by what I have learned of the histories of disease throughout the United States (\$ 969 d, 1005 l, 1005l, 1006 f, g).

All this, however, is inferable, as it respects my own experience, from what appears in this work, which was published originally as late as the year 1847, and continued in repeated editions without modification; and I advert to the subject now, that I may not be misapprehended (§ 1004, $1005\frac{1}{2}$). It may be also proper, in consideration of the preference which I have hitherto given to the experience of others as being of greater weight than my own, to repeat (§ 1025), that I have, doubtless, seen as much of the effects of Bloodletting in private practice as has been witnessed by any other Physician during my professional life, which extends over a period of more than forty years, while also I have been always unremittingly and actively engaged, up to the present time, in the practical duties of Medicine.—Note p. 763, Notes Ff p. 1135, Gg, Hh.

§ 1068, c. Moreover, having adverted in this work to the treatment which I pursued in a case of inflammation affecting one of my own family (§ 992, d), and a case of remittent fever of which another member was the subject (§ 870, aa), I shall state briefly the practice which was pursued in one of simple pneumonia with which I was seized in March, 1847, as supplying evidences, at least, of my profound convictions upon all the questions before us. The first remedy adopted was the loss of blood to the extent of about two pounds. This was followed by five grains of Blue Pill, and in a few hours afterward by about two drachms of Castor Oil. Some ten hours after the Bloodletting, the symptoms having recurred, I was again bled to the extent of about 24 ounces. I now took at intervals of about four hours, half a grain of Ipecacuanha and two grains of the compound powder, the latter to allay the cough. Alterative doses of Tartarized Antimony were also employed at intervals of two or three hours, but not to the extent of producing nausea. About twelve hours after the last Bloodletting, the symptoms having again returned, though in a diminished degree, twelve large leeches were applied to my chest, and the bleeding maintained for several hours (§ 925, a). This was towards the decline of the day. The Alteratives were continued, and a Blue Pill of about five grains was taken. On the following morning, the symptoms having again increased, I desired my medical friend, Dr. James C. Bliss, to bleed me again. It was his opinion, however, that I might recover with the aid of the other means alone. I replied that I did not fancy the risk when I had so sure and safe a remedy in the farther loss of blood, and expressed a wish that he would "carry out upon myself the practice which I had inculcated in my medical writings, and which I taught my Medical Class." I had then in mind.

in § 650-653 a-d. The result shows the distinction between the instant application of sound principles and the tardy conclusions from complicated facts.

also, the experience which prompted the remarks just antecedently published in § $892\frac{1}{5}i$, $1006\ b$, c. I was accordingly bled to the extent of about 20 ounces, when the symptoms vanished entirely and permanently (§ 955, b).

On the ninth day after the last Bloodletting, when my medical friend called in the morning, he found me outside of the house, at my early morning exercise of sawing wood (§ 992, b, c). No other medicine was taken, and no blister was required. It should be said, also, that my digestion had been impaired for a long time antecedently, and that it became subsequently much improved (§ 1007, b).—Note III p. 1138.

§ 1068, d. One case more, as farther illustrating the object of this Section. It may be interesting, also, on account of the usual fatality of the disease, and the embarrassing circumstances by which the case was surrounded; while it will go to show what have been the practical habits of the writer, and that he has inculcated nothing upon the subject of Bloodletting that has not been warranted by his own experience. The patient was one of our medical students, E. P. Johnson, M. D. of the Class of 1850–51. I found the fauces of an intense redness, tumefied, and attended with a complete inability to swallow. Any effort at deglutition was arrested at once by the suffering which it produced. There was great constitutional irritation, much restlessness, pulse rapid, hard, and small. Strength prostrated. No difficulty in respiration (§ 140, 525–530, 689 l, 718).

There was, at this time, a great deal of clamour in the Profession against Bloodletting under any circumstances; and as this case would be well known to the Class, I felt some regret that it had fallen into my hands, particularly as I apprehended a fatal issue, and that discredit would be brought upon the principal remedy upon which I saw that I must rely. Nevertheless, I sat the patient half erect in his bed, and bled him till syncope began to approach. The quantity of blood taken was about 40 ounces; an extent of the remedy which I practice only in severe forms of inflammation.

In a few minutes afterward the patient was able, after repeated and painful efforts, to swallow a dose of Calomel and Jalap—about 10 grains of the former and 20 of the latter. This operated within a few hours, but brought no relief. The throat remained of the same intense redness, and the patient could no longer swallow. Accordingly, on the same day, I bled him again to approaching syncope, when I abstracted about 32 ounces more of blood, the head and shoulders, according to my habitual practice, being elevated. Nothing more was done till the day following, when, finding the patient no better, I directed the application of twelve large Leeches to the anterior part of the neck. They executed their office well, and the bleeding was kept up for some four hours, but the patient was apparently worse in the evening. But, having done so much in so short a time, I concluded to await the issue of the last remedy till morning. Nothing could be swallowed, and the inflammation was too intense for a blister (§ 893, p). Curiosity was now on tiptoe about the bleeding, and the general merits of this remedy were to be judged by the issue of the case. I supposed, indeed, that it had been already condemned. Added to this, I felt an extreme degree of anxiety to save the life of my patient. So, on the following morning, one of the coldest in the Winter, I arose at four o'clock, and walked to the house of the patient, about a mile. What then happened I shall relate circumstantially.

as it may be of benefit to some others under similar exigencies, and, as I trust, for many generations to come.

The scene, when I entered the room, was in every respect of the most dispiriting nature. Johnson was apparently moribund. His mind was abolished, the fauces as red and tumid as ever, and a thread-like pulse running with almost countless rapidity. I stated to his nurse and classmate, the now Dr. Oliver, that the only remaining chance was from a farther abstraction of blood, but that the probability of immediate death was so great that it was inexpedient to risk any farther the reputation of this important remedy. That something, however, might appear, at least, to be done, I directed a large blister to be applied to the nape of the neck and shoulders, and left the patient with the expectation of finding him dead at my next visit.

No sooner, however, had I left the door of the house than I was beset by a painful consciousness that I had been in some measure deterred from a repetition of bloodletting by a fear that the patient might die under the operation, while, on the contrary, one more application of the remedy might save his life. In any event, it could but shorten it a little. This train of thought continued till I had walked some quarter of a mile on my return home, when I found myself almost unconsciously return-

ing to carry out the practice which my judgment prompted.

I then stated to Oliver that I had returned for the purpose of giving to Johnson his last chance, and that if he died in my hands it was a sad responsibility to which all should be willing to submit, irrespectively of any consequences to themselves, or to practical medicine; that it was our duty to give to the patient the only remaining chance for life, even though the means employed might be likely to hasten a death which would be otherwise certain.

The head and shoulders of the patient were raised, and about twenty ounces of blood were abstracted (§ 973-980). The relief from the last bleeding was such that the patient could swallow water within an hour afterward; and from that time his convalescence went forward steadily

and rapidly (§ 955 b, 994, 1000–1001, 1005).

The circumstances of the foregoing case, particularly the nature of the disease and attending symptoms, rather than the quantity of blood abstracted, impart to it its principal interest. In several cases of inflammation of the brain and lungs, where I have had the same successful conflict with disease, the bleedings have been much more numerous, especially in phrenitis, and the quantities of blood abstracted have averaged a greater amount at each application of the remedy. There has been, also, in the cases to which I refer, the same exigency for the last bleeding, and the same apprehension that it might hasten death (§ 756 b).

P.S.-1860.-In addition to my statement as to croup (§ 1058 p) I place it upon record that I have never failed of abstracting blood in pneumonia, phrenitis, and puerperal fever, and with rare exceptions in erysipelas, and that I have never lost a patient af-

fever, and with rare exceptions in erysipelas, and that I have never lost a patient affected with either of the last three diseases, and one only with pneumonia (a child of three years), and this, in my judgment, from insufficient blood-letting (§ 1005, 1058 q). Finally, as nothing carries conviction like reliable statistics, and as no city has a more salubrious climate than New York, and to place its excess of mortality on the prevailing "stimulating plan," let us look at the statistics for January, February, March, and April, 1860, as obtained from the City Inspector's Report. During those four months there were 8283 deaths, of which the following are some of the startling details: Predmonia, 602; Bronchitis (pneumonia?), 180; Cuoup, 312; Consumption, 1159; Scaralet Fever, 1000. Probably about 1 in 11 from Pneumonia of all the deaths (see note, p. 760).—Of London it is said by the Dublin Medical Press—"that the deaths from pneumonia in London number from 130 to 150 weekly, labout the same proportion as in the city of New York]; but that in Dublin a death from that disease is of rare occurrence."—(Boston Med. and Surg. Journ., May 31, 1860). The "stimulating plan" prevails in London, the lancet is used in Dublin.—See Notes F p. 1114, Mm 1141.

PHYSIOLOGY OF THE SOUL AND INSTINCT.

DEMONSTRATION OF THE SOUL.

§ 1069. In the year 1848 I published an Essay on the "Soul and Instinct, Physiologically distinguished from Materialism." this is the only attempt made, so far as I am aware, to demonstrate the substantive existence of the Soul and Instinctive Principle upon physiological grounds; but, on the contrary, has been evaded (§ $350\frac{3}{4}$, gg), and as the question is intimately connected with many of the great topics embraced in these Institutes, and forms an important subject in Physiology, I shall incorporate with them the essential parts of the demonstration contained in the Essay.*

§ 1070. The evidence turns wholly upon physiological facts; my essential premises are relative to the Nervous System, and are admitted by all. They are variously presented in this work, but must be now stated briefly to render the argument at once intelligible, and that it may appear a consistent whole. This involves, necessarily, a recapitulation of facts which have been hitherto presented in different parts of this work.

§ 1071. 1. The brain, or an equivalent ganglion, is the organ of intellectual, instinctive, and all perceptive functions (§ 197–199½, 455).

2. The spinal cord, and the nerves which depart from it, are, among other uses, the organs through which the Will transmits its influences to the voluntary muscles (§ 227, 233, 258, 473–475, 476 c, 500 dd).

3. The ganglionic or sympathetic nerve is designed, in part, to connect together, in harmonious action, the involuntary organs, or those upon which life essentially depends. It is also through this nerve, especially, that the passions display their effects (§ 96-108, 113-117, 126-130, 455, 523-524, and references there, and INDEX II., art. Mental Emotions).

4. The cerebro-spinal and sympathetic systems of nerves are intimately blended with each other, so that the brain, or its equivalent, is the great centre of both systems, and the spinal cord a less general centre, while the ganglia of the sympathetic nerve are now well ascertained to be local centres to that nerve. Of this character, also, are, doubtless, the semilunar and other plexuses, while, in very recent times, it is rendered probable that certain nerves are special centres of nervous influence (§ 1037, a); all of which, however, are more or less subordinate to the brain (§ 487 g, 497, 499 a, 516 d, No. 9, § 520–523, 524 d, No. 4, § 1038). Whatever, however, may be true of these local centres, it is of no importance to my demonstration.

In consequence of the foregoing union of the two systems of nerves, the cerebro-spinal system has certain organic influences upon the essential organs of life (§ 110-117). Physical irritation of the brain and spinal cord may be thus transmitted directly to the voluntary and involuntary organs (§ 473-494, 1039); and the Passions, but not the Will, by their direct action upon the brain, may readily affect these essential or involuntary organs through the sympathetic nerve (Index II., Men-

tal Emotions).

The influence of irritations of the expanded extremities of the sympathetic nerve may be also transmitted to the voluntary organs through the circuit of this nerve and the great nervous centres, as seen in the

^{*} Some things that I have said of Instinct lead me to state that the original edition was distributed extensively, and acknowledged in the literary journals in 1848.

convulsions of children arising from dentition, intestinal irritation, &c. So, too, on the other hand, from the same intercommunication of the cerebro-spinal and sympathetic systems, irritations or other affections of the voluntary organs may be felt by the involuntary through influences transmitted by the sympathetic nerve ($\frac{454-475}{5}$, $\frac{500-524}{5}$, $\frac{891}{5}$, $\frac{1}{5}$,

5. The familiar fact must be next stated, that the nerves are composed of two kinds, one of which transmits the influence of the Will and of the Passions, and the effects of other causes, from the nervous centres towards the circumference, while the other kind transmits impressions from the circumference to the nervous centres. The first of these two orders of nerves is concerned in the development of voluntary and many involuntary motions, and are hence called excito-motory nerves. The second order are nerves of sensation, or sensitive nerves, though the influences transmitted by them to the nervous centres are felt, in the natural state, only when propagated through the nerves which supply the organs of sense (§ 201–204, 227, 451–453, $462-475\frac{1}{2}$, 500, 1037 b). It should be also remarked that, while some of the two orders of nerves are wholly or mostly of one kind or the other-either excito-motory or sensitive—a very large proportion of the nerves are composed of fibres of both orders, though perfectly distinct from each other in arrangement and function. This double order pervades the entire body, and has brought the physiology of the nervous system within the range of the most exact experiment, and has become the foundation of many important laws, which are as clearly ascertained as any in astronomy. The two orders of nerves, or fibres of compound nerves, never interchange their functions, one of them being always employed in transmitting impressions to the brain and spinal cord, and the other as purely centrifugal in its office (§ 466).

It is also important to understand that my demonstration is concerned particularly with the system of excito-motory nerves, both voluntary and involuntary, or those nerves or fibres of compound nerves which transmit influences from the brain towards the circumference. Nevertheless, many examples of nervous influence will be introduced, in which the other kind, or sensitive nerves, are equally engaged along with the excitomotory, as contributing to the demonstration. It may be said, too, that when the latter are alone concerned, as in all acts of the Will, or when the Passions operate, or when motions follow in the voluntary or involuntary organs from mechanical or other physical irritations of the nervous centres, the projection of the nervous influence is in a direct line from the central parts of the nervous system towards the circumference, and generally terminates there (§ 245); but that, when both orders of nerves are interested, the influences are circuitous. With these last, however, I shall be employed only for supplying illustrations in proof of the substantive existence of the Soul and Principle of Instinct, and of their modus operandi through the excito-motory nerves (§ 500 dd, i, k).

§ 1072, a. Having thus stated our anatomical and physiological premises, I shall next endeavour to render the demonstration of ready comprehension by the uninstructed in the physiology of the nervous system by stating many illustrations derived from the operation of physical causes to serve as parallel examples with the operation of the Soul and Instinctive Principle.

We have seen that influences may be transmitted from the brain and spinal cord towards the circumference by impressions made directly upon

those centres, as when they are irritated by mechanical or other agents, or when the Will or Passions operate (§ 1071, No. 4). We have seen, also, that impressions may be made upon these centres through irritations produced in distant organs, and then reflected from the nervous centres upon other distant parts, and even upon the parts from which the irritations proceeded originally (§ 512-524, 1071, Nos. 4, 5). This transmission of influences from remote parts to the nervous centres, and which is perpetually going forward between those centres and all other parts. in natural states of the body (§ 111-113, 455-458, 500), evinces the great and inscrutable susceptibility of the brain and spinal cord, and enables us the better to comprehend the action of an Immaterial Substance upon the brain, and its transmission of influences to all parts of the body. An immense proportion of the natural influences upon the great nervous centres (and they are unceasing and manifold beyond the compass of imagination) proceed from distant parts, and are circuitous in their ulti-They begin in the expanded extremities of the senmate destinations. sitive nerves, or sensitive fibres of compound nerves, in all parts, by which they are transmitted to the nervous centres, where they make their wonderful, and, as it were, infinitely complex but unfelt impressions, which are then reflected from those centres upon other parts through excito-motory nerves or the motor fibres of compound nerves (which are also called, in such cases, nerves of reflexion). The palpable exceptions to these reflected influences, and where the transmitted impressions terminate in the central parts of the nervous system, are normally confined to the impressions transmitted from the organs of special sense, as in seeing, smelling, &c., and when no mental emotions are excited (\$194-204, 450-451).

We will now come to our examples of transmitted and reflected influences, which are clearly exhibited in respiration, in vomiting, in contractions of the iris, in the permanent contraction of the sphincter muscles, in spasms from teething, or from irritations of the intestines, &c.

In breathing, for instance, two principal nerves are concerned, and the diaphragm is the principal muscle which is moved. The sensitive fibres of the pneumogastric nerve, and more or less of the sympathetic, are the parts through which an impression, arising from want of atmospheric air, is transmitted to the nervous centres, which is then reflected upon the diaphragm through the phrenic nerve, and calls it into action. Now, the phrenic nerve is also the excito-motory nerve through which the Will operates upon the diaphragm in voluntary respiration. The other respiratory muscles have similar relations to the pneumogastric and to other excito-motory nerves, and the Will operates as readily upon the intercostal muscles as upon the diaphragm. But the diaphragm is conspicuously marked in this respect, and its importance is inferior only to that of the heart. For farther details relative to the coincidences between voluntary and involuntary respiration, and voluntary and involuntary coughing, &c., I would refer the reader to \$ 500, c-nn; and to § 902, b-y, for the physiology of vomiting, its various modes of production by physical causes, and the exact coincidences (as in involuntary and voluntary respiration) between their effect and vomiting brought on by Mental Emotions.

In seeing, there occurs the very complex example of the motions of the iris, which are entirely of an involuntary nature; while the iris stands in the same relation to perfectly distinct nerves as does the diaphragm. In the former case, the optic nerve not only conveys the impression to

the brain which is recognized by the mind, but it is also the sensitive nerve for the iris, by which the pupil is exactly adjusted to the degree of light, while, according to some, the excito-motory nerve of the iris goes from the ciliary branches of the lenticular ganglion through its communication with the third pair of cerebral nerves; but, according to other and later observations, "the cervical sympathetic is one of the motor nerves of the iris, and the spinal cord is the origin of the nerve fibres going from the sympathetic to the iris."* The brain is the bond of union in all the cases; but, for an obvious final cause, the iris, unlike the diaphragm, is withdrawn from the Will (§ 514, k). the stimulus of light, however, is indispensable to the natural contraction of the iris, and is so far unobserved, it will be readily understood by the uninformed how a similar impression upon the pneumogastric nerve in the lungs is necessary to the involuntary motions of the diaphragm; and since the transmitted impressions to the brain excite no sensation, either in the foregoing cases, or in all the endless variety of reflex actions in which physical causes institute the movements, it becomes evident that it is no objection to the supposed action of an immaterial substance upon the brain that it is not felt.

We have now seen that the principle is exactly the same, whether impressions made directly upon the nervous centres give rise to motion in parts that are voluntary or involuntary (§ 1071, No. 4, and references there), or whether the impressions upon those centres be occasioned by influences transmitted to them from remote parts, and which, by reflexion, equally give rise to motions. But, in all the latter cases, the resulting motions are involuntary, as are all in the other cases excepting such as arise from the operation of the Will. But, in the case of the direct impressions, it is particularly important to remember that the motions which are produced by the Passions are essentially involuntary, and, therefore, so far exactly coincident with such as arise from irritating the brain mechanically (§ 1071, No. 4), and by our demonstration, the same, also, with any reflex movements that arise as the effect of impressions propagated from distant parts upon the nervous centres.

It may be finally added that the two nervous centres, and both orders of nerves, co-operate together in giving rise to motion in the organs of organic life, so far as organic actions depend upon the nervous system (§ 172, 176, 177, $226-233\frac{3}{4}$, 1041); while only the brain and spinal cord and the excito-motory nerves are concerned in developing the motions which are brought about by the Mind, or the Instinctive Principle, or by Mechanical or other direct physical irritations of the brain. ordinary respiration, for example, the sensitive fibres of the pneumogastric nerve are indispensable for the transmission of an exciting influence from the lungs to the nervous centres; but in voluntary respiration the pneumogastric nerve is not concerned, but only the nervous centres and the excito-motory nerves of the respiratory muscles. In the former case, the irritation of the nervous centres proceeds from the lungs, and therefore does not originate in the brain or spinal cord, and so of all reflex actions: in the latter case, those centres are directly irritated by the Will. In the former case, also, a cause totally distinct, and originally remote from the nervous centres, makes its impression upon them, and calls the nervous power into operation; while in the latter case, or that of voluntary res-

^{*} Brown-Séquard remarks that "this fact is well established by Budge and Waller." —Exp. Research., p. 10, 1853; also, § 1042.

piration, precisely the same nervous influence is brought into action, and through the same nervous channel, by the Will, and therefore, by parity of reason, by a cause as distinct from the brain and spinal cord as is the cause of the irritation in the former case. The first is true of all involuntary motions when the nervous centres are irritated by impressions propagated from other parts; and the last is true of all voluntary motions, and of all the involuntary, when the irritating cause is applied immediately to the centres.

These coincidences in results of irritations of the brain and spinal cord as brought about by irritations of parts remote from those centres with such as follow their direct irritations by *mechanical* causes, and the coincidences between the effects of indirect irritation of the nervous centres, as in involuntary respiration and vomiting by emetics, with the same effects of the mind in voluntary respiration and vomiting occasioned by disgust, and the coincidences, also, between the effects of mechanical irritations of the brain with such as ensue upon the operation of the mind and its passions, and a general concurrence of the coincidences, throughout, as to a manifest *cause* irritating the nervous centres, as well as a general coincidence in results, form the groundwork of this demonstration $(227, 228, 233\frac{4}{5}, 475\frac{1}{2}, 476 c, 500 c-p, 647\frac{1}{2}, 844, 902 l, 1067 aa)$.

§ 1072, b. Let us now be critically understood, both here and in former places in this work, when speaking of the Passions as elements of the mind, and as producing involuntary effects. It certainly is not intended to be implied that they are not more or less associated with acts of intellection, and, perhaps, always brought into operation by some act of the Mind properly so called. This is also doubtless true of the Will. which appears to depend more or less upon the previous exercise of reflection, comparison, and judgment, in man, but moved into action in greater independence in animals—that is, instinctively. This remark may apply, also, to the Understanding (§ 241 b, 243). If, however, the Passions and the Will be the results of intellectual processes, the former, by their great variety and their peculiar operation in organic life, while the latter and all the higher faculties of the mind are excluded from that department of life, and the sameness of the Will, throughout, in principle and results, evince an individuality that renders them equivalent to elements or properties of the Soul and Instinctive Principle. as precise and peculiar in their phenomena as any admitted faculties, and their results are far more strongly pronounced. They must, therefore, be taken as equivalents, and as the only practical ground of discussion. All beyond is, at least, metaphysical (§ 243-246, 903, 1067).

But the question which is thus raised, in anticipation of any caviling, has no bearing upon our demonstration, nor upon any of the topics discussed in these Institutes. It is equally immaterial whether the Passions and the Will be distinct elements of the Soul and Instinctive Principle, acting independently, or summoned into operation by the higher faculties, or whether they be, respectively, the concurrent results of those faculties. In the latter case, they would be employed in a collective sense; and, as the results are the same as if they were distinct entities, and entirely different from other manifestations of Reason and Instinct, they are as properly designated by the specific names of Passions and Will, and the former resolved into Love, Hatred, Anger, &c., as any of the Faculties upon which they may depend are known by other names. They may be called mere Emotions; but still they would belong to mental processes, and that is enough for all the purposes that can bear any

relation to physiological inquiries, or to our present objects. It would be, indeed, equally to our purpose, were it conceded that the stimulus which gives rise to the Passions emanates from other organs than the brain, since they operate through the medium of the nervous system, are under the control of the mental faculties, and are palpably associated with them either as co-ordinate elements or as resulting emotions. The remote stimulus, upon this hypothesis, simply rouses the mind into action. The conclusions, therefore, which I shall have predicated of them can not be affected by any hypothesis of a metaphysical nature, nor by any supposed involutions of other organs with the brain (§ 167 f, 175 b, 183, 188 a, 227, 230, 232, 241–245, 476 c, 500 f–p, 902 l, 1067. Also Indexes, article Will).—Note Hh p. 1138.

Having thus disposed of this question to meet any subtleties of the speculative philosopher, I shall now interrogate the physiological facts as to the individuality of the Will as a property of the Soul and Instinct, when it will be found that it is in no respect the same complex emanation of either as the Passions. It is not obedient to any analogous laws, nor does it operate through the same mechanism as the Passions. It is distinguished from the Passions by the simplicity and precision of its results, by its great final cause, by its operation in animal life, and through the cerebro-spinal system, while the Passions operate mostly in organic life and through the sympathetic system. In all these respects the Will is on common ground with Judgment and Reflection, while it is the most important and uniform characteristic of the Instinctive Principle throughout the animal tribes (§ 476 c, 500 h).

§ 1073, a. It is allowed by all that some invisible, intangible principle exists in the Nervous System, commonly known as the Nervous Power, which is extensively concerned in the processes of animal organization; and I have endeavoured to show that this power is a vital agent, which is very variously brought into action either by physical or mental causes, and that when motion is produced by direct or indirect physical irritations of the brain, or by the Will or the Passions, it is in consequence of the development of this nervous power, and the direction of its influence upon the organic properties of the parts that are brought into motion. It operates equally in organic and animal life, but through very different channels and with very different results. It is most important in the organic life of animals, though its greatest final cause is relative to animal life. Its transmission to the former is through involuntary nerves, whether it be consequent on the operation of physical causes, or when the Passions disturb the organs in that department of life; and it is through the cerebro-spinal or voluntary nerves that the Will operates upon the organs of animal life, and when injuries of the brain or spinal cord, or when the Passions affect these organs. Such are the general facts (§ 1072, a). When the Will produces muscular motion, it is by developing the nervous power, and transmitting it to the voluntary muscles, when it stimulates the muscles, and brings them into action through their own inherent power. And just so of the Passions, and of physical causes. There is no wandering of the Will or of the Passions into the organs which they affect, as has been always vaguely supposed, no more than of physical agents when, on being applied to the nervous centres. they excite analogous motions (§ 233). It is also important to understand that the nervous power, by whatever cause developed, is liable to act with intensity upon the brain (\$230, 509, 950, 1040). I have also

endeavoured to show that the nervous power is developed by the mind in all acts of intellection, and that there is then an associate action between this power, the brain, and the mind; though beyond the analogies supplied by the Will and the Passions this may be hypothetical (§ 234).

But all that is embraced in this Section, whether as to the nature of the nervous power, or its mode of development and action, or whether it have any existence, is unimportant to my demonstration (\S 234, e-h). It simply facilitates an understanding of the phenomena upon which the demonstration depends. (See INDEXES, Articles Nervous Power, Sym-

pathy, Remedial Action, Organic Life, &c.).

§ 1073, b. I may say, also, that in the Medical and Physiological Commentaries I have endeavoured to show that the Nervous Power forms a bond of union between the Soul, the Principle of Instinct, and the Brain, and that this Principle is instrumental not only in the results of Sensation as set forth in the present work, but in the acts of Intellection. The phenomena of the Nervous Power in developing voluntary motion when the Will operates, and of the Passions in their demonstrations in Organic Life, supply many forcible evidences of the instrumentality which I assign to the Nervous Power in the concerted action between the Soul, the Principle of Instinct, and the Brain. (See Indexes, Articles Will and Mental Emotions.)

§ 1074. From what has been now said of the ground of my reasoning, you begin to perceive the consequences which must logically follow. You begin to discern the force of the analogy between the effects of those elements of the mind (or emotions, if it be preferred, § 1072, b), the Will and the Passions, and of mechanical and other physical agents when applied to the brain. You see, already, that if the brain be influenced by SOMETHING when physical agents acting upon it give rise, in consequence, to motion in the voluntary muscles, and in the heart, bloodvessels, stomach, &c., so must it be equally influenced by something, and that something must be equally an exciting and analogous cause, when the Will gives rise to voluntary motion, or when the Passions affect the action of the heart, produce blushing, or excite vomiting, &c. From the exact identity of effects in the two cases, there must be an analogy among the causes and their modus operandi; and therefore the Soul and Principle of Instinct (of which the Will and the Passions are prominent characteristics) are as much distinct causes as are the mechanical irritants or other physical agents which determine the corresponding movements. I say, that such is your mental constitution you cannot resist this conclusion, however prone you may be to materialism. Here is an animal whose brain is shocked by a blow or irritated mechanically, and spasms follow in the voluntary muscles; and you see that the Will is even capable of imitating that convulsive affection. Here is another whose brain is irritated by the application of alcohol, and you see the heart beating more actively as a result; and here is a third whose heart is as quickly enfecbled in action by the application of tobacco to the brain, just as it is excited by joy and anger in the one case, or depressed by grief and fear in the other (§ 481 a-h, 487, &c.). You also witness the same spasms in the voluntary muscles from the operation of the Passions as arise from mechanical causes when affecting the brain (§ 486, 487 g). Consider, for example, a paroxysm of hysteria, where convulsions of the voluntary muscles are brought on by some mental irritation, and where they are exactly the same as when produced by disturbing the brain mechanically.

Consider, also, how greatly analogous are these mental paroxysms to the convulsions that proceed from teething and intestinal troubles; and how exactly alike are the voluntary and involuntary acts of respiration, one of them being determined by the direct action of the Mind upon the brain, and the involuntary act by an impression transmitted from the lungs to the brain. How precisely the same, also, the involuntary contraction of the sphincter ani and its contraction as effected by the Will, and where the same philosophy is concerned in respect to causation as in the voluntary and involuntary acts of respiration (§ 500 o, 514 f, g). Consider, too, among the inexhaustible examples, the variety of effects which result from the operation of an emetic, as set forth in $\S 902$, g, and the same effects as produced by a blow upon the head—all consequent upon an irritation of the nervous centres—and then compare them with the same results which ensue when vomiting is produced by disgust, and even by its recollection; and compare many of these results with the effects of Fear—the bounding action of the heart, the small and rapid pulse, the half-suspended respiration, the pallor of the skin and the copious perspiration, the flood of urine, the hurried movements of the intestinal canal, the ghastly countenance and frightful eyeballs, the trembling of the voluntary muscles and the prostration of their power; or, compare the results of many physical causes, such as constipation of the bowels, with the effects of Grief, either so influencing the nervous centres as to undermine digestion, or so acting upon the brain as to overthrow the mental faculties; or consider how Hope, succeeding to Grief, will, like tonics, cathartics, shower-bath, change of climate, &c., influence the nervous centres in yet another manner so as to restore that digestion which Grief had impaired. And what makes the tears flow, when Grief, or Love, or Joy, or Anger, is in the ascendant, just as they do when snuff or other physical agents irritate the nose? Why does the mouth water at the sight of a bountiful feast, or on scenting its odour, or from its expectation alone, just as it will on chewing horseradish or tobacco? Why will the sight of a pill-box, or offensive odours, or startling or other unpleasant sounds, operate upon some after the manner of cathartics (§ 514 m. $844 \, a, 892\frac{3}{2} \, b, 944 \, b, 951 \, c$? It is palpable enough, that, in one series of the cases the effects are owing to some physical cause irritating the brain and spinal cord, and which are totally distinct and different from those nervous centres; and, can any one be so regardless of the plainest rule of philosophy as to suppose that the corresponding results, in the other series, are not equally due to some cause which is alike distinct and different from the nervous centres? All of them are the most familiar facts that engage our attention; but such as are relative to the mind have engaged us only as facts.

§ 1075, a. We now revert to our statement relative to the nervous power (§ 1073) in pursuit of a common exciting cause by which all the endless but analogous phenomena to which we have adverted are brought about. It is readily granted that the mechanical and other physical causes are not transmitted to the parts which they influence through the medium of the nervous system, and we must therefore look for some intermediate cause by which the remote effects are produced. It is of no importance to our present objects whether this cause be galvanism, or a nervous fluid, or nervous power, or a vibration of the nervous fibres, &c. (§ 184 b, 234 a); and, from the analogy in the effects of the Will and Passions, it is equally clear that these elements or emana-

tions of the Mind are not transmitted to the parts affected, but that they must operate through the same intermediate exciting cause as the physical agents. These unquestionable coincidences, therefore, not only place the external and internal primary causes upon common ground as substantive agents, but are demonstrative of their operation through some common cause appertaining to the nervous system. This is also farther sustained by the simplicity and consistency of Nature in her fundamental institutions, especially where the mechanism is the same, although there be great diversity in the remote causes and results.

Nor do I entertain any doubt, however much the physical school may look upon this question as an affair of "spiritualism" (§ 1034), that the facts, which are of such an endless variety, so distinctly pronounced, and so perpetually before us, will be universally allowed to establish the interpretation rendered in these Institutes of the modus operandi of the nervous power. There is not a phenomenon relative to the nervous system which the doctrine will not explain, nor is there one which can be consistently or intelligibly explained by any other. (See Indexes, Articles Nervous Power, Sympathy, Remedial Agents, Will, and Mental Emotions.)

It is also evident from my premises, that, if the movements which are excited by the action of physical causes upon the brain be only remotely due to those causes, and not to any primary change in the brain (which includes the transmitted as well as direct impressions), it must equally follow that the effects of the Will in developing voluntary motion, and of the Passions in modifying the action of the heart and bloodvessels, and other organs, cannot be due to any original, primary changes in the condition of the brain, but, of necessity, to some causes as distinct from the brain as are the physical. But, as this is the great point in materialism, and forms the chemical doctrine of intellection, let us admit that the remote effects brought about by physical impressions upon the brain are due to simply some physical change in the organ, and that, therefore, the corresponding manifestations of the Will and the Passions are equally owing to simply physical changes in the great nervous centre, it will still follow just as logically that there must be in the latter case as much an efficient cause for the cerebral changes as there is allowed to be in the former.

§ 1075, b. So far, then, the analogy is complete. But, in the case of the physical agents the causes are of a passive nature, and require other agencies to bring them into operation. How different, on the other hand, with the Will and the Passions! Here the causes are entirely self-acting, originating their own actions in the Sensorium Commune. This, in itself, establishes a radical distinction between the nature of the Soul and Instinctive Principle, and of all physical causes, and is utterly fatal to materialism. The self-acting nature of the Soul and of Instinct, and especially of the rational faculty, transcends greatly the Principle of Organic Life, which requires the operation of stimuli to rouse it and maintain it in action (§ 75, 136, 1881). Nay more, the Will and the Passions are among the most efficient causes in calling into action the Principle of Life; and being, in this respect, upon common ground with all vital stimuli, the materialist will see in this analogy an insuperable proof of the substantive existence and self-acting nature of the Soul, and how, also, the same analogy distinguishes the Soul completely from the Principle of Life, with which it has been confounded even by eminent Vitalists. The group of the facts is here so very comprehensive, and

so demonstrative of the two most important problems in intellectual and organic philosophy, that I pause in this manner upon the subject. But so far as action is immediately concerned in the two cases an analogy obtains, and we may reason upon that analogy from the self-acting Soul to the existence of an active Principle of Life upon which organic motions depend (§ 234, 1034). But, we shall seek in vain, throughout the wide range of Nature, for any direct similitude with the manifestations of Reason or of Instinct; though, if we pass the limits of Nature, we may discover in the results of Creative Energy that analogy with the Soul which shadows forth the Image of God (§ 234, a-h).

§ 1076, a. What has now been said is equally applicable to materialism, whether it regard the manifestations of mind as a chemical phenomenon, or as elaborated from the blood; and these are the only hypotheses which have any intelligible foundation. They must, therefore, be now

considered more specifically.

The chemical supposes that all acts of intellection, all manifestations of the Will and the Passions, all the impulses of Conscience, and all Adoration of the Deity, are results of "the chemical action which the elements of the food and the oxygen of the air mutually exercise on each other" (§ 349 e, 500 n, 1054). This is the hypothesis of combustion. But enough has been said to show the impossibility of referring the phenomena to a chemical process without, at least, an attendant cause to institute the process. This, however, is farther examined at § 500, nn, o, to which I would refer the reader; and what will soon be said of the doctrine of mental secretion will be alike applicable, in principle, to the chemical hypothesis, and will cover the whole ground.

§ 1076, b. But there is a class of Philosophers who have endeavoured to render the chemical doctrine acceptable by admitting something like a Soul, which is supposed to act as a predisposing cause of that combustive process upon which the phenomena of Reason and Instinct are said to depend. But it may be readily seen that the hypothesis is

illusory.

In the first place, the supposition of the dependence of thought, &c., upon any chemical process necessarily places the agency of the supposed principle, in its relation to the phenomena of Mind and of Instinct, upon exactly the same ground as the simple chemical hypothesis; for the results would still be chemical and nothing more. If oxygen unite with another element, and result in combustion, it takes place under a special law, and an exact chemical product ensues, which neither the Soul can alter, nor imagination affect. The only part which the Soul would take. according to any analogies borrowed from Chemistry, and which is necessarily the part supposed, would be that of exerting merely a predisposing affinity among the elements. This predisposing influence is meant to embrace whatever may be supposed to result from its action upon the doctrine of catalysis (§ 409 j, 350^{3}_{\pm} a-e). In this only view of the subject, the chemical tendency of the Soul would no more react upon itself than that of platinum, and the only result would be (in chemical phraseology), a combustion of the elements of the brain, just as when hydrogen and oxygen gases are submitted to the catalytic action of the metal. And so of any other given chemical change. It always terminates in one way.

Whenever, therefore, oxygen unites with the phosphorus of the brain, according to the material doctrine of intellection, whether chemical or

chemico-spiritual, it can form no other compound than phosphorous or phosphoric acid, whatever the supposed activity of the combustion; or, if it unite with those other combustible elements of the organ, carbon and hydrogen, the resulting compounds must be carbonic acid in one case, and water in the other; or, at most, a special triple compound of those elements. An exciting, or predisposing, or any other agency of the Soul, even were the soul a material substance, would in no respect affect these results; and to imagine that the Soul enters into either combination, and is yet in perpetual operation, per se, would be a chemical absurdity. Whatever consideration, therefore, may be given to chemical processes thus instituted as the source of ideas, &c., it can be in no respect different from that which attributes them to one of an uncomplicated nature, whether the soul be immaterial or material.

The difficulty will be readily appreciated, both here and in regard to organic products, which are equally ascribed to a chemical process (for these doctrines are essentially alike), should it be attempted to call in the aid of the Soul, or the Principle of Life, in any of the manipulations of the Laboratory. They are so far on common ground; and, if the Soul can promote combustion in the brain, or in any way modify its results, or the Principle of Life subserve the chemical hypothesis of organic results (according to Liebig), they should be equally competent out of the body, so only they could be brought into external operation. But no imagination can surmise the possibility of applying them in a chemical manner, and, least of all, eliciting by the aid of the Soul the phenomena of mind from the most ingenious devices of Organic Chemistry. On the other hand, however, there is no difficulty in regarding the Soul as a cause

acting through the vital constitution of an organ, and thus originating all the phenomena of mind; while, in so doing, we get rid of an unnecessary, as well as an unmeaning and mischievous multiplication of causes

(§ 171–221).—See § 455 a as to final causes of the union of Soul and Brain. The Chemico-Spiritualist is thus coerced to the alternative of ascribing all intellectual and instinctive functions to the immaterial principles in their co-operation with the vital constitution of the brain, or to deny the existence of those principles (whether immaterial or material), and throw himself exclusively upon the simple chemical rationale. If the doctrine stand, it must be upon its own merits, and not through any sophistry that may seem like a leaning towards the common faith of mankind—no gilding the material device—no concession to what may be considered the innocent but obstinate belief of the spiritual theorist, in the trust that he may finally discern the reality of his delusion.

Again, farther: the Organic Chemist maintains that all the processes of life are owing to the same combinations of oxygen with phosphorus, carbon, hydrogen, and nitrogen, as are supposed to give rise to intellection. The brain is thus placed on common ground with all other parts. Why, then, are there no manifestations of mind or instinct in the liver, intestines, or in the bones where phosphorus abounds? Or, turning to the accommodating Chemico-Spiritualist, I may ask, if the Soul or Instinct make all the difference as regards intellectual and instinctive manifestations, what makes the difference in respect to the corporeal phenomena? Nor is that all. If the brain be considered the source of intellection in its organic condition alone, how are facts treasured up, and ever present from childhood to decrepit age? As the brain, like all other parts, is constantly subject to renewals, the facts should go with the parts upon

which they are impressed, if the organ alone be their receptacle. Why, again, are the events of childhood fresh to the Octogenarian, when those of the day are speedily forgotten? Why may memory be trained with a special reference to particular subjects, and to a forgetfulness of others, or disciplined to a general compass of knowledge? Materialism must here be consistent and stand on its own philosophy. But the Soul, on the other hand, as also the Instinctive Principle, being one of an unchanging nature (as proved by these very facts), holds fast the treasury of knowledge, or the improvements it may gain (§ 180).

And here we come upon a demonstration which, were there no other objection, would be fatal to materialism in either of its shapes; for one hypothesis supposes that intellection, &c., is the result of the combustive process, and the other, of secretion. In either case, therefore, all ideas

should be as evanescent as the processes themselves.

Finally, such as are disposed to follow the Author any farther upon this particular question will find in former parts of this work many suggestions which have a direct bearing upon it, as in $\$350\frac{3}{4}$ e-n, p. 180–192.

§ 1076, c. And now, as to the other branch of materialism, or that which regards the phenomena of mind, &c., as the products of secretion. This question has been incidentally discussed in these Institutes, but with other objects than are now contemplated. As it bears, however, as well upon the chemical as the functional doctrine, and as it is desirable to amplify the argument, and that it may appear as an integral part of the

present demonstration, I shall introduce it here (§ 175, c).

I have there said that in former works I have presented certain facts which go to the conclusion that the Soul is a distinct, immaterial substance, and that the Instinctive Principle of animals is equally a distinct substance from the brain. I then proceeded to comment upon the main argument of the Materialists, drawn from analogy, that the mind, like the gastric juice, bile, &c., is only a product of the organic functions of the brain. I have there shown, also, that the supposed analogy is destitute of foundation. It might be sufficient, in proof of this, to simply say that the Mind and Instinct are wanting entirely in every known attribute of the products of other organs, and are sui generis in all their characteristics. But there are other more absolute characteristics which completely destroy the supposed analogy. What, for example, is the efficient cause of the production of bile, saliva, &c.? Certainly the blood, in connection with organic structure and organic actions-chemical, if you please. While these processes go on, bile, saliva, &c., are produced uninterruptedly; or, if arrested, it is from the failure of the organic processes. But it is just otherwise in respect to the Mind and the Instinctive Principle. All their manifestations are completely suspended during sleep, and often with great instantaneousness, or, to meet any sophistry about dreams, I might say half suspended; and yet the organic functions of the brain continue to move on as perfectly as those of the liver, the lungs, &c. Indeed, were any change of this nature to befal the brain, it would be particularly manifested by some consequent modification of all the organic actions, especially as those of the Mind and Instinct undergo complete suspension. The continuance of all the organic results proves that organic life is every where in perfect operation; while, by equality of reason, the suspension of all results in animal life proves that an agent, upon which these results depend, has ceased to operate. In one

case, organic functions must go on without interruption, and therefore the moving causes upon which they depend must be in perpetual action. In the other, it is ordained that the organs peculiar to the division of animal life shall have periodical repose (though only as it respects mere animal life), and, therefore, by parity of reason, their spring of action is constitutionally fitted for quiescence as well as action, and this, as it respects sleeping and waking, corresponds with the alternations of thinking and not thinking during the waking time. The various gradations in the suspension of mental and instinctive functions from their quiescence in the waking state to profound slumber concur, also, in this part of our demonstration. Nor is it at all important to our purpose whether there ever be a complete suspension of the intellectual or instinctive functions.

But again: suppose some change in the organic condition of the brain, as the cause of sleep ($\S 500, n$); what is it, I say, that so instantly reinstates its organic functions when we pass from the sleeping to the waking state? What arouses the organ to its wonted secretion of Mind, or what, in the other case, restores the combustive process? Certainly not the blood. Are there any analogies supplied by the liver, or by any other organ? Do you assume that some imaginary stimulus is propagated upon the brain from other organs? Then I ask what brings this into operation, and under such an infinite variety of unique circumstances? In what conceivable manner does it modify the organic functions of the brain so as to excite the secretion of Mind, or how, in the other case, does it start the combustive process? Do the functions of any other organ supply the slightest ground for such a conjecture? Will it interpret the reason why sleep is so prolonged in the habitually indolent, or, contrasted with this, why the laborious and exhausted student often sleeps less than others, whatever their occupation? Is it said that this is the result of habit, or of self-discipline? In either case it is an admission of a self-acting Principle, which brings itself and the brain under these influences, and therefore it is necessarily that Principle which rouses the brain from its state of suspended animal functions. It is a case, too, very strongly to our purpose, for it denotes a remarkable cultivation of the spiritual part, which enables it to spring into active operation from a dormant condition in habitually exhausted states of the body, while the brain, according to materialism, should resist all wakefulness till that organ, and all other parts, are fully recruited by repose (p. 329–332, § 500, n-p, Liebig). But the Materialist is not convinced by the difficulties attendant upon sleeping and waking; and again, therefore, I ask him, What is it that directs the special combustive or secreting process in all the acts of volition, in all the acts of intellection; or what brings them into operation? What are your conceptions of Creative Energy? Are not the results of Mind, however separated from Infinity, precisely analogous to those which are everywhere seen as the offspring of an Infinite Intelligence? But, if you admit a God, you will not reason from your debasing doctrines of the human mind to the Attributes of your Maker? And I ask the Materialist what answer he will make as to the condition of our Lord before His appearance upon the earth, and as He was "manifest in the flesh?" Was there no Spirit there? Nothing but material eliminations of Mind from the blood, or a conflagration of the elements of the brain? For so you must have it, and so it is meant, where the same mental phenomena are so interpreted in man. Nay more; so complete is the analogy between the acts of ratiocination and those of the Creator, as

seen in the humble designs which are devised and executed by man, and which, indeed, is all that we know of Him except from Revelation, it would unavoidably follow, upon the doctrines of materialism, that all the Designs of the Almighty Being were equally the results of chemical or organic processes! Or is this to be excluded from the pale of "science"?

The questions and arguments now propounded must be answered consistently, and in some conformity with the hypotheses drawn from analogy. If that can be done (this simple physiological requisite alone), then it must be conceded that the analogy is entitled to the gravest consideration. So, on the other hand, should the hypotheses fail in this indispensable requisite, materialism must stand convicted of sophistry, insincerity, and a leaning to infidelity.

Here we might bring our demonstration to a close as it respects the existence of the Soul, and its power of instituting actions in connection with the material fabric. But there may be some who may be inclined to follow us in a more extended inquiry than has now been presented, especially as the demonstration will continue to be predicated of admitted facts and principles, as set forth in these Institutes.

§ 1077. What will be presented in the present section is mostly a series of physiological examples which concur with the foregoing in

enforcing the conclusions at which we have already arrived.

It has been seen, extensively, that impressions upon the nervous centres, by which the nervous influence is developed and determined with various effects upon distant parts, are all upon a par, in principle, whether they result from agents applied directly to the centres themselves, or be transmitted to them through the medium of parts remotely situated, or whether the Will and Passions make their demonstrations. Take some of the examples among the muscles which are both voluntary and involuntary. Let these be, again, the respiratory muscles, including those of the face. Now, their several movements are liable to numerous modifications, some of which are natural, as in sneezing, coughing, yawning, laughing, and others more or less morbid, as asthma, hiccough, &c. In all but two of these cases the movements depend upon the excitement of the nervous power through some sensitive nerve, which are generally the sensitive fibres of the pneumogastric, and the reflection of that power from the brain and spinal cord, through motor nerves, upon a part of or upon the whole of the respiratory muscles. In each process there is a special irritation of the nervous centres, and in each the nervous influence is brought into operation in a peculiar manner, and according to that manner is the nature of the movement. In Asthma, a stronger irritation is propagated from the lungs to the nervous centres, and a more intense motor excitement is reflected from the centres upon all the muscles of respiration (often including those of the face), than in ordinary breathing, and in some cases the Will comes to the aid of the irritation propagated from the lungs. Here, then, it is seen that a prompting of the Mind and the physical causes are brought into immediate co-operation in rousing the brain and spinal cord. The physical cause is insufficient to excite the requisite movements of the respiratory muscles, and therefore the Mind lends its assistance. Both act in perfect harmony together; nor can the slightest difference be observed in the results of either. excepting as the Mind acts with greater energy, and brings the respiratory muscles of the face into action.

Now, upon the physical hypotheses of intellection, what is it that

superadds to the respiratory movements, in the foregoing case, a cause perfectly distinct from such as naturally governs the process? If it be said, fluctuating conditions of the brain, what is the cause of those fluctuations? Why is there at one moment only a moderate degree of the supposed combustive or secretory process, and at the next a greatly increased amount of one or the other, and this requiring as much a cause as the excitement of the brain in the involuntary act? And here we may again advert to the sphincter muscles as supplying a parallel example.

Take another illustration — the acts of voluntary and involuntary laughing. When the feet or arm-pits are tickled, laughing follows irresistibly in many, as the effect of an irritation propagated to the nervous centres by sensitive nerves supplying the skin of those parts (§ 514 d, The phenomena are the same as witnessed in ordinary laughing, where the Will and agreeable Emotions are the exciting causes. The former soon becomes painful, and then goes on in direct opposition to the Will. A man, for example, bound the limbs of his wife and tickled her feet till she died of laughing, just as some die suddenly of a strong mental emotion, "which," as Shakspeare says, "is as bad as die with tickling." And here I would ask the Materialist what other construction he can apply to the cases of sudden death from joy and anger than the powerful operation of some unseen cause upon the brain, and through that organ upon organic life? What other condition than a violent shock of the brain from a cause as distinct in its nature from the organ, as the hammer whose blow upon the head is fatal through precisely the same physiological influences? (§ 230, 455, 476 $\frac{1}{2}$ h, 478, 479, 500 f-nn, 507-509, 634, 902 l, 951 c, d.)

A case precisely parallel in its physiological rationale with death from mental emotions (last references) occurs in syncope, when it arises from seeing or hearing something offensive, or from the sight of a lancet. Here the immediate cause, as in the case of death from joy or anger, is the instant and powerful determination of the nervous influence upon the brain, heart, stomach, &c. (§ 230, 479, 507-509, 634, 951). But there must be something to develop that nervous influence in the brain, and the common sense of every one assures him that it is a conscious agent which does the work. But, for the fullest illustration of this subject, let us analyze the physiological rationale of syncope as produced by offensive odours. Here the Mind may have but little participation in the prostration of the heart, &c., but the effect be mainly due to the physical impression propagated to the brain through the olfactory nerve, and perhaps, also, the nasal branches of the fifth pair (§ 514, m), which impression, in itself, develops greatly the nervous influence. But the Mind may also contribute to that development; for, if the odour were not perceived, no syncope might follow. Thus, again, are associated the physical and mental causes in producing a common effect, while in the case of the lancet it is purely a mental emotion which determines the paroxysm. But, in respect to the odour, the Mind generally endeavors to resist its effects, and as syncope may happen in spite of the effort, it is evident that the depressing influence may be mostly due to the direct action of the physical cause upon the brain, just as we shall soon see how a strong light acting upon another pure nerve of sensation may produce sneezing; but I think more the mental emotion (p. 79, note).

Let us now connect with the foregoing facts the syncope which follows

blows upon the head, and it will be seen, as plainly as we see that the physical blow upon the brain is the cause in one case and the odours in others, that the Mind inflicts the blow in the remaining series, or that of joy, anger, the lancet, &c. The physiological effects prove conclusively, both in their nature and coincidence, that one cause is as much an agent acting upon the brain as the other, and that both are equally distinct from the organ (§ 514 m, 844 a, $892\frac{3}{4}$ b, 944 b, 951). In all the cases where the physiological effects are consequent upon mental processes, the Mind and the effects stand in the same relation as do the physical causes and their effects in the other cases, and where the effects are precisely the same in both series. To suppose the absence of a cause in the former is a physiological absurdity, and to suppose any other primary cause than the Mind, as a self-acting Agent, is a greater absurdity. Nay more, the Mind, the brain, and the cerebro-spinal nerves are absolutely indispensable to all voluntary movements, however true it be that the power by which the movements are accomplished is implanted in the muscles (§ 258-267, &c.); while the motions of organs in organic life may go on without Mind, or brain, and even without cerebro-spinal nerves (§ 261, 264, 455 a, $461\frac{1}{2}$ a, 478 b, 490, 1042).

I have said that in the several modified movements of the respiratory muscles mentioned at the beginning of this section, all but two depend upon irritations of the nervous centres propagated through sensitive nervous fibres from the lungs or other parts, and that, in all the cases, the same excito-motory nerves bring the muscles into action. The two exceptions are voluntary laughing and yawning. In the former case, the Mind, unlike involuntary laughing, rouses the brain without the intervention of any sensitive nerves, and determines the nervous influence directly upon the muscles of the face through the excito-motory nerves; which is also true of the bloodvessels of the face in blushing, and of the production of tears in weeping, though in the latter instances the nervous influence is propagated upon the face and gland through motor fibres

of the sympathetic nerve.

In ordinary yawning, which is exactly a modified form of respiration, the Mind may have but little or no participation in the act, but it may depend alone upon a physical impression transmitted from the lungs to the nervous centres, along, perhaps, with a concurring sense of uneasiness propagated from the voluntary muscles; or, if the Mind participate, as in its efforts to relieve a sense of weariness, the physical and mental causes act in co-operation, just as happens in severe cases of asthma. At other times, a very different chain of causation may be observed, and where, also, the mental and physical causes appear to identify themselves, as it were, with each other, as in sympathetic yawning, where one yawns on seeing or hearing another yawn, or in talking about it; for, in one case, an irritation is propagated both to the brain and Mind through the optic nerve, and in the other case through the auditory nerve, and simultaneously the Mind conspires with the physical irritations in exciting the nervous influence, and directing it upon the muscles of respiration. But a paroxysm of yawning may be readily consequent upon simply thinking about it, as will probably be the case with many on reading this statement; when the reader will, doubtless, feel quite assured that his mind is as exclusively the cause in this instance, as the physical irritation commonly is in ordinary yawning.

Just so, too, in respect to offensive odours, when they produce vomit-

ing instead of syncope. In the former case the Mind may be more interested in the physiological effects than in the case of syncope from analogous odours; since the odours may be so far different in the two series that disgust is in operation in one, but not in the other. A rose may occasion syncope when just plucked from the bush, but vomiting only when in a decaying state. The Mind, therefore, in the case of vomiting, and the nervous influence, are brought into simultaneous operation by the transmitted impression, and the Mind then co-operates with the physical impression and occasions a farther development of the nervous power, and thus increases the intensity of that degree which is created by the physical impression. But the odours may produce either vomiting or syncope, as also purging, by their own independent influence, and in opposition to all resistance of the Mind; or, on the other hand, the Mind, as in breathing, yawning, and coughing, may be adequate to the entire effect, for it will produce vomiting by reflecting upon the former action of the odour, and which may have happened years antecedently. Sympathetic vomiting, on seeing or hearing another vomit, is mostly of this nature; but here, too, as in the case of the odours, the mind alone may determine an act of vomiting by simply reflecting upon a disgusting spectacle which had at a former time upset the stomach (\dagger 230-233\frac{4}{3}, $475\frac{1}{3}$, 500 c-p, 514 b, c, l, m, $647\frac{1}{3}$, 844, $892\frac{3}{4}$, 902 l, 1066).

To render the foregoing readily intelligible to the student, farther explanations will be made. He has become sufficiently enlightened by the demonstration to see that, in all the examples, the Mind is necessarily a substantive agent, acting of itself upon the brain. The nervous influence which it develops, in the cases of vomiting, is exactly equivalent to that which arises from the action of an emetic upon the stomach. There is, however, one more link in the chain of causation in the former than the latter case; for when the Mind is the exciting cause, the nervous power is first projected upon the mucous coat of the stomach, where it irritates the organ after the manner of an emetic. This irritation is then reverberated, as in the case of the emetic, upon the nervous centre, and thence reflected upon the abdominal muscles, diaphragm, and muscular coat of the stomach, by which they are brought into spasmodic action. When vomiting is produced by tickling the throat, the Mind has no connection with the effects, but the physiology is so exactly coincident with that which is relative to the Mind, that it goes with the rest in showing how the Mind is necessarily a substantive, self-acting cause. The chain of causation is the same here as in the case of the Mind, only the first development of the nervous power is produced by the irritation of the throat (§ $233\frac{3}{4}$, 500 e-k, 514 b, c, 894-896, 902 e-g).—Note D.

Whenever vomiting springs from disturbance, or disease, or any novel conditions of organs remote from the stomach and brain, the same chain of causation obtains as in irritating the throat; the point of departure being the affected part, and the nerves supplying it are the organs of transmission to the nervous centres. When the irritation, in these physical cases, is thus made upon those centres, it is exactly equivalent to the mental irritation when the Mind is the remote cause of vomiting, and the subsequent steps in the process are exactly the same in all the cases. The sickness and vomiting which spring from sailing, whirling, riding, &c., depend upon the same chain of influences. In these examples, the remote impressions which are propagated to the brain arise, in part, from mechanical effects upon different organs, and they are, in

part, exerted directly upon the brain itself. In these instances, however. the Mind often participates in developing the nervous influence, through some emotion that grows out of the physical influencee; as may be known from the fact that a strong determination of the Will to resist sea-sickness will often prevent its occurrence, especially the act of vomiting; while, on the other hand, if one has made up his mind to be sick, he will surely be so, though in the midst of a calm. In the former case, the development of the nervous influence by the motion of the vessel falls short of the intensity necessary to vomiting. And so of other analogous causes; and so, too, when offensive odours, disgusting sights, &c., operate, or when memory turns them again upon the stomach. In all such cases, and in various conditions of disease (§ 1067), the Mind, by resolving not to co-operate with the physical causes, or keeping down fear and other depressing emotions, may often yield no little protection to the stomach. In this counteracting influence of the Mind we have, also, another exemplification of its substantive existence and self-acting nature, as contrasted with its co-operation with the same physical causes in other cases (p. 78, § 167 f, note, 1067 aa).—Note D p. 1114.

In section 514, l, an example occurs, corresponding with the foregoing, in which the physiology of sneezing is shown when occasioned by the Sun's light impinging upon the retina. Here the circuit of nervous influence is very complex. And now observe how perfectly the Mind will do the same thing; since, by thinking intently upon a former paroxysm, the mind will develop the nervous influence by its own direct action upon the brain—will determine that influence upon the lining membrane of the nose, and give rise to the same irritation as the light of the Sun, or as in the case of snuff; when the subsequent steps become alike in the several examples. The only apparent difference, so far as effects are concerned, between the physical and mental causes, consists in the self-acting nature of the latter. The Mind, the nervous influence, and physical agents are all on a par in principle, as it respects their character of substantive causes in relation to effects (§ 234, f, $475\frac{1}{2}$, $647\frac{1}{2}$, $500 \ k-p$).

Such are plain examples among a multitude of analogous ones. But we must consider others less obvious, that Materialism may not oppose us with specious problems in organic philosophy. It may be asked, for instance, How will you explain the movement of the limbs during sleep upon your doctrine? The ready answer is, exactly upon that doctrine, since the facts are of the same nature with those already stated. In these cases the act may be either voluntary or involuntary; but, throughout, it arises from some impression made upon the nervous centres. Sleep may not be so profound as to suspend entirely the action of the Will; or, in other cases, the motion is owing, remotely, to some impression propagated from the limbs to the nervous centres. These remote impressions arise from some constrained position, or analogous cause, and may not awaken perception, or call the Will into exercise; though, doubtless, in most cases the Will is roused into action. If involuntary, the phenomenon is then coincident, both as to cause and effect, with the motions of decapitated animals, as when, for example, a decapitated turtle draws up its leg on being pricked, or as a bird flutters or runs on striking off its head. Here the nervous influence proceeds, of course, from the spinal cord alone; and the example is another clear illustration of the substantive, self-acting nature of the Mind (§ 451, c, d).

Let us next suppose that the Materialist will demand of us an expla-

nation, upon our general facts, of the influences which are concerned in sleeping in the erect posture, which is common to many animals. The physiology of voluntary and involuntary respiration, and particularly of the action of the constrictor muscles, and the exact coincidences between the voluntary and involuntary acts in either case, supply, respectively, an answer to the interrogatory. It is evident, therefore, that in sleeping in the erect posture, the muscles are placed by the Will in a state of tension which determines upon them an unceasing nervous influence after the action of the Will is suspended, and in a manner analogous to that which holds the sphincter muscles in a state of permanent contraction ($\S 514 \ g$, $516 \ d$, No. 6, $\S 902 \ k$). Indeed, there is always, as in the case of the latter, a certain degree of involuntary nervous influence operating upon the voluntary muscles, by which their antagonism is balanced. This is shown by the division of nerves, as when those of one side of the face are divided, or paralyzed, the muscles lose their relation to those of the opposite side. Another example occurs in the wry-neck.

The same explanation is applicable to the contracted leg of the bird, in roosting.* The whole principle, in all its variety of manifestations, according to the nature of the animal and the uses of parts, has its foundation in consummate Design. The modifications in different species of animals correspond with those of Instinct, and are full of instruction to the contemplative mind. Their final cause belongs to the same inscrutable system of Designs as the varieties in Instinct itself; and, if we may not trace out the exact mechanism, or the remote causes in all the cases, there are a multitude of analogous facts which have been clearly ascertained, and which as clearly interpret the less demonstrable problems to every right thinking mind (§ 234, a-h). The route of the nervous influence among the organic viscera, and even among the voluntary muscles, is often eluding the knife of the anatomist (§ 2333); and well may he sometimes despair of success, yet rest in the conviction that Nature operates by general laws, when he considers the fact that the Will determines its influence upon whatever voluntary part it chooses, isolating many intermediate nerves, or electing one only and far remote from its own seat of operation. And so he shall equally find it in organic life, where the Passions play their part, at one moment upon the heart, at another upon the skin, or kidneys, or genital organs, or raise the blush of modesty in the capillaries of the face, or strike us dead in an instant; and he may witness far greater demonstrations of the same principle in the operation of remedial agents (§ 852-888, 894-905).—Note A.

We draw to a close. If the discussion have been protracted, it has been due to the magnitude and the novelty of the subject. We might have rested the demonstration upon the operations of the Mind in its function of willing alone, were there a ready acquiescence in the logic of facts. Through these endless manifestations we almost see the Thinking Being enthroned upon the great centre of the nervous system, wielding at its inexpressible pleasure, and through the instrumentality of its organ, that amazing power which as far surpasses electricity in the compass and variety of phenomena, as the effulgence of Reason transcends the glimmerings of Instinct. The Will but commands (§ 1072, b), and Reason may be chained for hours to some abstract process, or tumultuous passion settles down in tranquil submission. With inconceivable rapidity of action it directs all the muscular movements which form the various feats of dexterity, the flight of animals, and the melody of song.

^{*} See § 500 dd, and Article Roosting, Index II.

And let us consider, also, as we ponder upon these things, how exactly the mind graduates the force of every muscle which it brings into action, varying through every imaginable degree from the slightest touch to the death-struggle of the combatant (§ 234 c-h, 235).

Who, then, shall be so unjust to his Reason as to imagine that all this wonderful display of a single function of the Mind is the material product of chemical mutations of the brain, or of any organic function of that organ, and without a conceivable cause of the cerebral process!

DEMONSTRATION OF INSTINCT, AND ITS DISTINCTION FROM THE SOUL.*

§ 1078, a. In what I have said in the former part of this work of the distinct nature of the Soul and Instinctive Principle, and of their connection with the main central part of the nervous system, my remarks have referred to their immediate relations to the body, as established through the cerebro-spinal and ganglionic systems (§ 234 f, 241, 500, &c.). At section 500, p, the deductions are made from a variety of facts, thoughnot altogether susceptible of direct proof. They involve a critical analysis of the various phenomena of which they are predicated, both in their relations to Reason and to the mere Principle of Instinct. But, however some acts of intellection in man may require the co-operation of the brain more than other mental processes, there can be no doubt that every act of the Mind and of Instinct is the result of an inscrutable concurrence between the self-acting cause and the organ over which it presides. It may be now said, also, that the brain is subservient to the Soul, independently of its relations to the body, in all its higher functions, while it manifests no such subserviency in animals; nor have I any doubt that all the facts warrant the conclusion that the nervous power is as well concerned in the functions of the higher faculties as it demonstrably is in the acts of the Will and the Passions. The instrumentality of the brain in the former case comes through the property of the Soul which is known as perception, and to which the senses are subordinate. The same property belongs, also, to animals; and so far as mere sensation is concerned, or as it may give rise to volition in its simple relation to animal life, the results are apparently the same in man and animals. But it goes no farther in animals, though in man Perception, as resulting from sensation, is the great fulcrum of Reason, and the fountain of intellectual knowledge. But that knowledge garnered up, every avenue to the Mind may be shut, and the harvest of facts remains, and may be now multiplied, cultivated, embellished by the exercise of Reason alone upon the organ through which the elementary knowledge had come. It may now summon a host of intellectual images, and render them tributary to those abstruse processes by which the laws of the Universe are scanned, and Mind itself analyzed and understood. This is abundantly manifested in the early displays of genius, where knowledge from external sources is just in its dawn. It is fatal to the doctrine of cerebral images.

But no such phenomena ever marked the highest cultivation of Instinct. It is all Instinct with animals, while this Principle is only feebly shadowed forth in man (§ 241). And this leads me to indicate the most fundamental distinction, in a physiological sense, between the Soul of man and the Instinct of animals; nor am I aware of any well-founded exception to the distinction which I make. Among the latter, the whole sum of instinctive processes is limited exclusively to the wants and the uses of the body. Whatever may be the fundamental cause, it is in complete operation at

the moment of birth, when its dawning has scarcely begun in the human race (§ 241, c). It is as perfect and comprehensive in the Ant as in the Chimpanzee. Each species of animal, and all the individuals respectively, carry out an ordained plan of existence, and this is the compass of their knowledge. From that particular path Instinct never diverges. It has no higher aim in the brute than the mere perpetuity of organic life, and it never operates without manifesting effects, either active or passive, in the mechanism of animal life. That is its grand characteristic, and its broadest contradistinction from the Mind of man. It terminates there; and Reason, therefore, must prompt the conclusion that the Instinctive Principle perishes with the body. But how different with the Soul, which spans the sciences, rolls up its vast acquisitions through all generations, and sees in itself the "IMAGE of God." All its noblest functions have no relation whatever to the uses of the body. The untutored Savage has all the perfection of life that is enjoyed by a Newton, and greater instinct. He may become a Newton without a gain to his physical wants, but with some loss of his well-disciplined instinct. Here, in the exercise of Reason, all physiological analogies fail, while every impulse of Instinct demonstrates its subordination to physiological laws. When Reason operates, there is no participation of the nerves, as in the case of Instinct, no influences seen upon any part of the organism. We look upon its manifestations as emanating apparently from itself alone. And since there is nothing in the manifestations of the Will when it operates alone in the processes of Reason that denotes any influence upon the animal mechanism, as is always the case in animals, and since, also, that influence is strongly displayed in man when the action of the Will refers to the organs of volition, this distinction between its intellectual and physical functions corresponds exactly with my inductions in regard to the general constitution of the Soul, and the relation which it bears in other aspects to the body. Hence, we may again conclude incidentally that, by parity of reason as it respects the uses of Instinct, the Soul, which in its highest faculties is useless to the body, will continue to exist without the aid of organic life. And, if I may deviate, for a moment, from my physiological ground, to final causes of a moral nature, I would refer to the manifest design of animals for the human race, as a farther proof of their absolute extinction when those ends are fulfilled; and, on the other hand, to the noble and sublime objects of man in his no less obvious companionship with God, as equally conclusive of the perpetuity of his being.

Nevertheless, the analogies between the Soul and the Principle of Instinct are such (§ 241, b), that if one be a distinct, substantive, self-acting agent, so must be the other. But their great practical final causes, independently of our other facts, are broad, fundamental distinctions between them; nor have these distinctions, within my knowledge, been hitherto indicated. It is only, however, a display of the common law of analogies which prevails throughout organic nature. The coincidences and distinction between Reason and Instinct are far less remarkable than the corresponding analogies and distinctions which are supplied by organic life in its greatest extremes; for there is not a single organic function of a comprehensive nature performed by man that is not equally so by the lowest plant. With greater reason, therefore, should we argue the identity of Man and Plants than of the Soul and Instinct* (See Note p. 873).

^{*} As an example of the assumptions and sophistry of those who reject the Soul, take

§ 1078, b. I am finally conducted to other and still more definite contradistinctions between the Soul and the Instinctive Principle, and where it will probably appear, also, that the brain co-operates less in the higher acts of intellection than has been commonly supposed. But the Mind, in all its functions, is not only more or less dependent upon its associate organ, but the influences which it is capable of exerting upon it in consequence, and thence upon the whole organism, are among the facts which form a broad distinction between the Soul and the Instinctive Principle. Nor can it be doubted that the full exercise of the Mental Faculties, as well as of Instinct, requires, in a general sense, a natural condition of the brain or its equivalent; and the greatest displays of the former are apt to be seen where the organ is developed beyond the common standard. To these general facts, however, there are important exceptions, several examples of which, as arising from organic disease and injuries, may be seen in Medical and Physiological Commentaries, vol. ii., p. 139, note. Equally true is it, also, that, from the co-operation of the Soul and the brain in the processes of Reason, excessive exercise of the Mind is felt injuriously in the organs of organic life, and too often permanently felt. The proper development of the brain is, also, arrested; and thus, in its turn, the Mind suffers a corresponding injury. Our general premises lead to this conclusion, and our primary schools confirm the principle in a lamentable amount of broken constitutions and smothered intellect. This, too, is one of our evidences of the substantive, selfacting nature of the Soul; and although the Instinctive Principle is equally self-acting, we here come upon the remarkable distinction that nothing like the foregoing has ever been witnessed from the severest discipline of Instinct. The Soul alone supplies these phenomena; and, from its incessant operation in undermining health, or disturbing the natural action of the organic viscera, it must be regarded as separating the Soul and Instinct widely from each other.—Note Hh p. 1138.

And this leads us to observe another and greater distinction; for, while the development of the Mental Faculties is retarded by overtasking the Mind in early life, just the contrary effect obtains in animals. By untiring zeal, and the lash of instruction, Instinct is often susceptible of influences in the *infancy* of animals, and *only then*; but here, again, it is just the reverse with Reason in the infancy of man. This distinction is also of a radical nature when compared with the improvements of Reason at later periods of life; for what has been supposed to be a

the following, from the "Lectures on Physiology," by the able and eminent Mr. Law-

"If the intellectual phenomena of man require an immaterial principle superadded to the brain, we must equally concede it to those more rational animals which exhibit manifestations differing from some of the human family only in degree. If we grant it to these, we cannot refuse it to the next in order, and so on in succession to the whole series—to the oyster, the sea-anemone, the polypi, the microscopic animalcules. Is any one prepared to admit the existence of immaterial principles in all these cases? If not, he must equally reject it in man."

one prepared to admit the existence of immaterial principles in all these cases? If not, he must equally reject it in man."

This argument is often staring us in the face, and it is quite time that it should be silenced, although "prepared to admit the existence of immaterial principles in all the cases." But, waiving the assumptions upon which the conclusions are founded, it is evident that the analogy fails as soon as we reach those animals which exhibit no rational manifestations. So the argument falls upon its own ground. Nor is that all; for, as in most cases where an author is at fault about principles, Mr. Lawrence contradicts himself. Thus, is another place he says that

"Although the external senses of brute animals are not inferior to our own, and though we should allow some of them to possess a faint dawning of comparison, reflection, and judgment, it is certain that they are unable to form that association of ideas in which alone the essence of thought consists."

"cultivation of Instinct" is, in reality, no such thing, since it subserves no useful purpose, and manifests itself only under the special influences. respectively, by which the several impressions were originally produced. The "tricks," &c., of the animal, whenever there is a deviation from the natural operation of Instinct, require suggestions from the associate causes. Unlike the improvements of the Rational Faculty, the artificial conditions of Instinct do not operate without the excitements of the primary causes, or their equivalents, and then always in exact conformity with the nature of the external cause. In other words (for the distinction is important), Reason acts independently of remote causes; the artificial conditions of Instinct require the agency of such causes to bring them into renewed manifestations. In the former case the senses may not be interested; in the latter, impressions must always be made upon sense (as in seeing and hearing), and transmitted to the brain, or some equivalent nervous centre, when Instinct will operate in an automatic manner.* It is only a display of those low analogies between Instinct and the Soul to which I have referred. Imitation, in a higher sense, as seen in parrot-talking, belongs to the same principle. But in these cases it is more constitutional, on account of the natural prating of the bird. It thus becomes ingrafted upon its notes, and will therefore display itself as an offspring of nature, and as a matter of habit, and without any extraneous prompt-What is thus acquired from man by the parrot and magpie, and which has been supposed, even by Mr. Locke, to evince a Rational Faculty, is derived by other birds from other songsters, particularly by the American mocking-bird and cat-bird, who appropriate the notes of many other warblers. Now, there is nothing more in parrot-talking than in these last examples, and the latter is just as much an evidence of a rational faculty as the former. The examples go towards the illustration of our subject in showing how Instinct is adapted to the peculiarities of organization in different animals, while man, through his Rational Faculties, may originate an endless variety of vocal music, and construct languages for himself (§ 241, b).

§ 1078, c. Even the promptings of Instinct, which impel animals to search after food, whether for present or future use, have their origin in present sensations. What is prospective in this respect is just as impulsive as migration, and as little allied to the course of Reason. The same physiological influences of hunger, in regard to immediate wants, operate in the infancy of man, though with none of that discrimination which distinguishes the infant animal; for the human infant will as readily suck at all things else as at the breast. Its apparent instinctive impulses go no farther than the movement of the mouth; and that is all the display of instinct it evinces, unless farther shown by its cries when

hunger is unappeased.

Again: as soon as Reason obtains its development, it displays an endless variety of inventions for the sustenance of life, which are wholly irrespective of associations with the original physiological incitements, but which must be forever a recurring cause to the animal. Whatever similitude may seem to exist between the acts of Reason and the acts of Instinct in procuring food, or in providing for the future, organic influences are interested in the latter as often as hunger returns; and, so far as the processes are dependent in animals upon the inscrutable constitution of Instinct, they are contradistinguished from all the analogous manifestations in man by their undeviating uniformity in animals, and ac-

^{*} Rarey's system of horse-taming is a comprehensive illustration of the principle. All horses yield at once, and alike, to the foot-strap, as would a machine.—1861.

cording, also, to the species of animals, while, also, all the individuals of a species pursue a common and uniform way. Thus, many species lay wait to entrap their food, and although variously according to the nature of the species, all the individuals of a species act exactly in a certain way, while others pursue a different course, and neither takes forecast beyond the present sensation of hunger; while in some species which subsist on vegetable food, the principle operates seemingly after the sagacious

manner of Reason in providing for their future wants.

§ 1078, d. And here we come upon another, and very broad distinction between the Soul and Instinctive Principle; for, as admitted by all, the greater the development of the brain in man, so, in a general sense, are the manifestations of Reason, and therefore a forecast in animals in laying up food, if at all allied to Reason, should predominate in those which have the greatest amount of brain; and here, if in any respect, there should be the greatest display of Reason. But it is just otherwise with all the superior animals, who take no thought for the morrow, what they shall eat; while in the bee and ant, where there are only ganglia for the nervous centres, there is an anticipation of the future in providing for the young which surpasses any thing known of the human race. What variety, too, in the structures which they rear for their progeny, according to the particular species in each genus, but always the same with each species. And then the food—just as methodically of a precise kind as the act of providing it. The whole history of the instinctive acts of the elephant or the lion may be written in an hour; but Huber found a good-sized book necessary for the amazing operations of the common honey-bee. He described the doings of a hive, and that description tells the precise history of all past and of all future hives. The diversified acts of this insect, and according as it may be queen, male, or drone, seem like the complex movements of some elaborate machinery, which, when wound up, runs on in one precise way till it runs down. And still more estranged from Reason, and utterly beyond its grasp, is the return of the bee to its hive through miles of trackless air, and the unerring flight of the carrier pigeon; nor are any of the higher animals capable of this amazing achievement, which, also, grows immediately out of the physiological arrangements for acquiring food.

§ 1078, e. The correspondence between the peculiarities of Instinct and the mechanism in animal and organic life is so remarkably full and perfect in its design, and so unlike any of the manifestations of the Human Mind in their connection with the organs and functions of either division of life, that a glance at the former will contribute farther aid in distinguishing the Soul from the Instinctive Principle, and in proving the absolute existence of Instinct as a distinct essence of the brute creation. If we may any where detect the Rational Faculty among animals, it should be found in the phenomena that are relative to their

means and modes of subsistence.

Now it will be found that, in every species of animal, the promptings of Instinct in the pursuit of food have a direct relation to the peculiarities that exist in the organization of the stomach, and the modifications of the special endowments of the gastric juice in each of the species (as set forth in section 353), by which one species is enabled to convert flesh, another nuts, another hay, &c., into one homogeneous substance called chyme, and which, from man to the lowest tribes of warm-blooded animals, at least, is apparently alike in all, whatever the nature and the

variety of the food. But the agreement between man and animals is limited to that result in its connection with the digestive apparatus, and as it relates to the maintenance of organic life. What is true of the precise adaptations of Instinct to the organic conditions, and its invariable operation in one way, according to the nature of the animal, is in no way true of the Human Mind; for the latter operates, in this respect, according to acts which involve the exercise of judgment, reflection, comparison, &c., and very variously, also, according to individual suggestions of Reason, Passion, love of sensual gratifications, the exigencies of disease, &c.

Since, therefore, Instinct has its special constitution conforming to the organization of the stomach and the peculiarities of the gastric juice, we shall see how far it is related in its peculiarities to other varieties in the mechanism of organic life, by considering how all these varieties in every species, respectively, have an equally direct reference as the peculiarities of Instinct, to the special organization of the stomach, and special constitution of the gastric juice. If, therefore, such be the relation of the whole mechanism of animals, both organic and animal, to the special condition of the stomach and gastric juice in their adaptations to the varieties of food in the several species, it is obvious that Instinct in all the species, respectively, must be constituted with a corresponding reference to every part of the organic whole. Now, an intestine, claw, hoof, tooth, or any bone of an unknown animal being given, we may construct a skeleton, say from the bone, that shall be true to nature in all its parts. We may thus proceed to cover it with muscles, provide it with claws or hoofs, and special kinds of teeth, &c., and, lastly, we can tell from that tooth, or claw, or hoof, or other bone, what was the structure of the digestive apparatus, and to what kind of food the gastric juice was specifically adapted, and what were the peculiar Instinct and habits of the animal; so special is the adaptation of all other parts of the organism, both in animal and organic life, to the peculiarities of the stomach in every species, and so exactly conformable are the Instincts and habits of animals to all that vast range of physical peculiarities in the several species respectively.

The foregoing is also true of man as it relates to organization. But who could surmise from any part, or from the whole of his organism, that he is endowed with Rational Faculties, or with any thing more than what is common to brute animals? Here begins, abruptly, a total distinction between man and animals—nothing whatever in the mechanism of either to denote the ending of one or the beginning of the other. Nothing, indeed, but analogy, founded upon observation, enables us to affirm with certainty the same principles of extinct species of animals. Nothing but observation informs us of either the physical ormental functions; for neither could have been deduced from structure alone. yet analogy is so perfect a guide where the continuity of the chain is unbroken, that no error can arise in scanning the Designs of Infinite Wisdom, so far as they are submitted to human inquiry. But analogy in relation to Instinct snaps in man. This might render it difficult, if not impossible, to know the great fact, had all the species of quadrumanous animals become extinct before man began his observations in natural history. The subsequent discovery of the skeleton of a chimpanzee would doubtless have been regarded as an unanswerable proof that there had been, at least, other beings upon earth besides the human race who

had enjoyed the prerogatives of Reason, and so a descending analogy imagined down to the polypi.* But, the chimpanzee is a thousand times less endowed with Instinct than the honey-bee; and we have seen that the sense of instinctive promptings throughout all animal tribes is concerned about objects which Reason regards as only tributary to those immeasurably higher occupations of the Soul which have no relation whatever to those of the Instinctive Principle.—Note Pr p. 1142.

§ 1078, f. However the foregoing branch of our inquiry (§ 1078, e) may be pursued, it will always result in the same uniform way. Consider, for example, the correspondence between the Instincts of animals and their weapons of offence and defence; each species of animals, and all the individuals of a species, acting defensively or offensively according to the special weapons with which they are provided. These means of preservation have a direct reference to organic life, and Instinct, therefore, is adapted to the nature of the means. The various provisions are not only such as are actively employed, both for the purpose of procuring food and for self-preservation, like the weapon of the sword-fish, claws, the poison of serpents, &c., but others for the simple object of self-protection, such as horns, the quills of the porcupine, the armour of the rhinoceros, the sting of bees, the galvanism of the electrical eel, the ink of the cuttle-fish, &c. Again, certain animals, and many of them of inferior orders, as some species of cockroaches, some of worms, often affect the appearance of death when closely pursued; and when this is seen in one animal, it is, as in the preceding cases, common to all the individuals of the species. Many other animals that keep near the ground are protected by their colour, and the animal, when alarmed, lies close. In all the cases there is a manifest unity of designs which conspire together for the well-being of organic life. Whatever may be the means of defence, of offence, of flight, or of whatever variety or modification, they are adapted to all the mechanism in animal life, to special sensation, &c., and according to the whole will be the special promptings of Instinct.—Note C p. 1113.

§ 1078, g. Fear, therefore, operates in animals impulsively, while in man it is the result of judgment, reflection, comparison, and his modes of defence are suggested accordingly. Observe, also, another fact relative to fear, which equally separates Instinct from the Soul. The young animal will turn from danger about as impulsively as the adult, while the human infant will thrust its hand into the blaze of a candle sooner than it will seize the nourishment that is simultaneously offered. In animals, indeed, the most exquisite sensitiveness to danger prevails, transcending even the promptings of hunger. Its predominance is designed alone for the preservation of organic life, and such are their exposures, and so limited their conceptions, that it is made to operate with great uniformity and instantaneousness. In man, on the contrary, its impulses are comparatively feeble and slow, and so far as it obtains, it aims at a variety of objects which are determined by the decisions of Reason. The principle, in animals, is evidently allied to that characteristic which di-

rects their migrations, and the homeward flight of the bee.

The manifest dependence, in man, of a sense of danger, and his expedients for self-protection, upon the Rational Faculties, has led to comparisons of certain Instinctive perceptions of danger in animals, with a view to the identity of Instinct and Reason, of which one of the strongest is often seen in the elephant on crossing a bridge, or embarking on a steam-

^{*} Who will doubt this, now that the much-lauded work of Darwin On the Origin of Species has made its appearance? See p. 814. note.—1860.

boat, as he first presses the bridge or the boat with a single foot to learn their stability. But this example is peculiarly adapted to our purpose, since Instinct is here constituted with a reference to the weight of the animal, who would be otherwise exposed to frequent injuries; and the associations that are indispensable to safety are early formed. But they go no farther, and this particular demonstration is seen only in animals that may break a bridge or sink a boat. It is, therefore, only an instance of the ordinary impulsive associations which are always in operation in cases of danger, and is exactly similar to the careful tread of the smoothshod horse when about stepping upon ice, or the wariness of the fox and the rat in eluding the trap, or the various expedients of the squirrel in dodging the sportsman, or the cautious nibble of the fish, &c. The varieties in these examples are almost as great as the species of animals, and they all belong to the exquisite intuitive principle which warns them of approaching danger. It is often seen, indeed, in the aspect of mutual protection among animals of the same species, when it always operates according to the nature of the species. The crow has his sentinel, and the affrighted ant communicates its alarm by a peculiar touch of its companion, which spreads with rapidity from one to another, till the whole hive is quickly thrown into this paroxysmal movement. And now, if this analysis be pursued through an obvious series of analogies, it will be found that the habits of bees in relation to their queen, and many other remarkable problems in the history of Instinct, are allied to the principle which I have just considered.

§ 1078, h. Another shade of difference in the general principle occurs in an example which has been presented by Metaphysicians to illustrate the supposed identity of Instinct and Reason. It is that of a dog, who has appeared, when making for a drifting boat, to lay out the plan of first ascending the bank of a stream above the boat, that the distance between himself and the object may compensate for the motion of the water, which would otherwise carry him below his destination. I present the example in its strongest light, and as implying all that can be surmised of a rational process in animals. But, with all instances of a similar nature, it falls within the common laws of the Instinctive Principle, which are just so far operative, according to the species of animal, as shall subserve the exigencies of life. In the case of the dog, this animal is more or less addicted to the water (especially the individual in question), and his Instinct is therefore adapted to the emergencies that may attend that temporary mode of life. He early acquires, in consequence, an impulsive apprehension of the effects of strong currents of water, and is so far capable of forming associations as may be necessary to his safety, or to his natural wants. The instance of the boat is one of safety and of want, and is exactly parallel with that where all dogs will elect a bridge of 500 feet in preference to swimming the width of a The knowledge of the effects of a current of water exceeds but little that of its quality of wetting; and when, therefore, a dog is moved by the desire of bathing, he neglects the bridge and takes to the water.

Various prejudices and misapprehensions relative to supposed instinctive acts abound in the community, who are prone to the most favourable comparison of the brute with his lordly associate. The rarity of apparent evidences of Reason in brutes, and the enjoyment of what is thus unexpected and wonderful, lead the multitude to seize upon what is accidental and carry it to the account of Instinct. An example of this,

which has often gone the round of the public, is that of the elephant and the apple, where the tempting morsel, being just beyond the grasping range of the animal's trunk, was made, by a forcible projectile blow, to rebound within its reach from an opposite wall. This has been thought to be but little inferior to a game at billiards. But it was simply an act of irritation, the blow being designed in the same resentment as when an angry man loses all reason and castigates a stone that has caused him an injury.—Note P p. 1121.

§ 1078, i. The Speculatist points to the care with which animals provide for their young, and the great resemblance between them and man in parental attachments, as an evidence of the supposed identity of Reason and Instinct. But I answer that this is much more seeming than real, and that however the principle may have an ultimate reference to the well-being of organic life in the infancy of man, it embraces in him far loftier objects, and prompts to an endless variety of useful purposes in the care of his progeny which have not the least connection with the exigencies of life, but which, on the contrary, are relative to the culture, the enjoyments, the morality, the Religion, the eternal welfare of the Spiritual part. It follows them through all the stages and vicissitudes of life, rejoices in their happiness, and grieves for their adversities. When intercourse fails, every expedient is devised, from the tardy messenger to the electric telegraph, to impart renewed expressions of affection, and fresh hopes of prosperity. And how is it on the part of the offspring? Does not every heart beat responsively to the Divine command to "honour thy father and thy mother?" And can there be a broader distinction between the attachments of animals and of mankind than what Scripture implies and what man pursues? The very attachments which man contracts for favourite animals flow from the Divine sentiment which is impressed upon his Soul. And then all that display of sympathy and friendship among companions of mutual thoughts, or of heartfelt kindness towards the faithful and trusty servant, or the universal characteristic known as the sentiment of humanity-where, I say, shall we look for the dawning of these mental attributes in the constitution of Instinct? And wherein are the instinctive movements of animals towards their offspring related to human affections? Simply for the preservation of life, and thus incidentally for the perpetuation of the species, as conclusively shown by the total and abrupt disappearance of brute attachments as soon as the offspring can provide for and protect themselves, and this, too, at ordained times according to the species of animal. Nay more; parents and offspring mutually abandon each other at allotted times, and turn upon each other. The principle is seen in full operation, and in its largest extent, in the bird while hatching her eggs. She may be in expectation, though she may have had no more experience in the final result than the bee on its return after its first wandering from the hive; nor is there any more similitude with the operations of reason in the one case than the other; she will as readily sit upon counterfeit eggs as her own till her time of "reckoning" is up, and then abandon them.

§ 1078, k. The same distinction (§ 1078, i) exists between the love of the sexes in the human race and what is observed of the sexual relations in the brute creation, and is not less opposed than our other facts to the assumed identity of Reason and Instinct. Like all else in relation to the latter, the impulse is totally restricted to the perpetuation of organic life. In the human species the same impulse is as a spark in a blaze of fire. The principle of love takes in its scope the loftiest sentiments of Mind, and anticipates all the intellectual endearments of domestic society, and yields a grateful tribute to its munificent Author. If there be a low analogy, it is of the lowest grade, and is nearly lost in the sublimity of its intellectual accompaniments. Nor can there be a parallel suggested between Reason and Instinct more degrading to man, or more unjust to his Maker, or more characteristic of a perverted mind, than that which is so often drawn in respect to human and brute affections. Yet he who makes it has a better opinion of himself, and only thinks so of the rest of his race.

§ 1078, l. And this leads me to speak of the very remarkable distinction between the Soul and Instinctive Principle known as Conscience. I employ the term in its popular acceptation, as meaning the ability and the impulse of man to decide on the lawfulness or unlawfulness of his own actions and affections, and to instantly approve or condemn them according to their nature. Nothing like this has ever been observed in animals. It is purely intellectual, and has a clear reference to the moral, Religious, and social condition of the human race. It may be said, however, to be apparent in some animals, as when the dog, for example, manifests a sense of wrong when he surprises the game in a manner opposed to his instruction, or does other analogous acts. But this manifestation happens only under the influence of those physical causes which led him to act more habitually in a different manner. The sense of wrong does not originate from the act, or on account of the act, but is excited by the presence of his master, whom he associates with the suffering which he endured when his Instinct was undergoing discipline, and thus resolves itself into a dread of punishment. It is therefore exactly analogous to all the other functions of Instinct which I have indicated, and forms the limit of associations of which animals are capable.—Note P.

§ 1078, m. And what shall be said of that other principle, scarcely less universal and impulsive than conscience—a love of Fame and a desire to live in the memory of posterity? The question becomes ridiculous in its application to animals, and is hardly less so, in an abstract sense, as it relates to man. But, as an incentive to laudable action, it is a noble offspring of Reason, and as significant of the Soul's immortality it rises into sublimity.

§ 1078, n. And what of Religion? What of the universal desire of immortality? What of a sense of dependence upon a Superior Being? It may be safely affirmed that animals have no other knowledge of their own existence than what arises from present sensations; and should a chimpanzee be seen bowing even to an idol, it would be a greater phenomenon than the expostulation of Balaam's ass.

§ 1078, o. Even memory, as it belongs to animals, is nothing but an association awakened by some present impression upon the senses. It is indispensable, however, to many of their wants and habits, and hence is so strongly pronounced in many species that they will recognize objects after a separation for long intervals of time, particularly where strong impressions had been made, as between the dog and his master, and wild beasts and their former keepers. In man, on the contrary, memory is often relative alone to acquirements which the mind has made through its own processes of reflection, and they may be as vast and profound as the elaborate inductions which led to the discovery of the universal law

of gravitation, and thence to the calculation of the existence of the planet Neptune. Nor does memory, in man, require any extraneous aid, like the apparently corresponding function in animals. It is a rational function in one, independent of sense; an instinctive one in the other, and dependent upon sense. In one, it always involves an exercise of Reason, and often a vast complexity of ideas; in the other, it is simply relative to the single impression which had been transmitted to the brain by some external cause, and which can be recalled only by renewed applications of the same or analogous causes.* By extending the analysis in this manner, it will be seen that it is all Soul in man, and all Instinct in animals.

§ 1078, p. But the most curious problem in the history of Instinct is its natural mutations in certain animals, and which carry with them an abundant proof of the radical distinctions between that Principle and the Soul, and that the former is designed for the mere purposes of organic life. I shall therefore give to the subject a greater consideration than

would be otherwise expedient.

This characteristic is seen, especially, in animals that are subject to metamorphosis, though in many of the instances the changes of organization and the modifications of Instinct are far greater than in others. The strongest examples occur in insects, a large proportion of which have four stages of existence: the egg, the larva, the pupa, and the imago, with corresponding instinctive habits in the last three. Where the metamorphoses are most remarkable, as in the foregoing examples, some of the organs undergo mutations that require a change in the stimuli of life which could not be realized without corresponding adaptations of Instinct. This is also more conspicuously illustrated by the difference in the wants and habits of those animals which at one period breathe in the water with gills, or analogous organs, and subsequently in the air with lungs.

Now these metamorphoses are as much the exact result of determinate laws, ingrafted upon an original constitution of life, as the development of the human ovum, or the seed of a plant; nor are they in any respect more fluctuating or less circumscribed (§ 72, 1051); and so a corresponding law obtains in respect to Instinct, through which the promptings of Instinct shall harmonize with those modifications of organic life that distinguish the several stages of metamorphosis. In all the cases, from the plant to the insect, and from the insect to man, the metamorphoses or other developments, and modifications of life, take place in one uniform way, according to the species of animal or plant. A potential whole, embracing all the special conditions necessary to the progressive changes from the ovum, through the larva and pupa to the fly, and in all analogous instances, is as perfect in the most mutable tribes as in the ova of the highest order of animals, or in the seeds of plants; and, since there can be no departure from a precise and uniform succession of developments in any of the species, respectively, we also learn that there is no transmutation of species, nor even an introduction of varieties (§ 1051, primordial cell).—Note Pp p. 1142.

In respect to the various physical agents required by animals subject to metamorphosis, according to their several stages, the principle is alike ingrafted upon the ovum, and equally so in the case of man, by which his development is started by one kind of vital stimulus, and is farther conducted through fœtal life by another kind, while a variety obtain after independent life begins. It is a metamorphosis in all (§ 63–81).

This brings us to the particular application of our subject, the simple subserviency of Instinct to the exigencies of organic life. Here it is, in the well-marked metamorphic animals, that it is distinctly seen that all its modifications keep pace, pari passu, with the changes of organization, and that the law is exactly coincident with that which respects the changes of structure, and is designed alone to fulfil the necessities of the latter. They equally spring from a common principle of mutation implanted in the germ.

§ 1078, q. There remains to be considered the comparative independence of the Soul in the exercise of its highest functions; when, also, certain anatomical facts between man and animals will be reviewed for the purpose of contrasting them in yet other relations to the Soul and Instinct.

Although there be a co-operation of the brain with the Soul in all acts of intellection, it does not follow from what has been said that the Rational may not act in greater independence of the organ than the Instinctive faculty. Just otherwise, indeed; for my argument to this effect is founded, in part, upon the distinctions which I have indicated between the Soul and Instinct, and upon what I am about to say of the general coincidence between the brain of man and of the highest orders of animals, though an opposite conclusion has been deduced from this relation. But the inference as to the equal dependence of the operations of the Soul and Instinct upon a concurrent action of the brain or its equivalent has also depended upon a neglect of the distinction in their attributes, or an assumption that there is no difference. The analogy in such a case would be sound and conclusive so far as it respects man and the approximate animals. But our premises are indisputable, that all the higher acts of intellection, everything which falls within the province of Reason, have no existence in animals. It is the only thing, indeed, which essentially distinguishes man from the brute, and would be in itself conclusive against the somewhat prevailing doctrine that man was once a member of the quadrumanous race. We have also seen that Instinct is more comprehensive in many insects where a ganglion takes the place of a brain, and far more allied in its operations to the plans of Reason, than in the highest order of animals, and is often as mature in the new-born as in the adult being; and since, also, the organization of the brain of the higher animals is greatly like that of man, but without any of his intellectual functions, we must logically conclude that what is so absolutely peculiar to the Soul, and, as generally granted, allied to God Himself, acts in greater independence of the brain than does simple Instinct. But, so inscrutable are its connections, as well as those of Instinct, with the organ in which it resides, that I shall not trespass beyond the limits which are prescribed by observation. Our facts terminate abruptly at this point, and mystery begins. But we may pursue the facts, and reason upon them as upon the most tangible evidence. We will therefore interrogate other proof in support of my conclusions.—Notes Pp p. 1142, Qq p. 1145.

We have seen that every variety of cerebral structure, from its approximation to man's in the higher animals to its disappearance in a scarcely appreciable ganglion in the lower tribes, is attended throughout with undeviating and perfect manifestations of Instinct, though according to the nature of the animal, while they are only dimly seen in the human species. This, in respect to Instinct, is conformable with all analogy as it regards other organs where the results depend upon anatomical structure

acting through the principle of Organic Life. There is every variety, for example, in the organization of the liver, from its greatest elaboration in man and the higher animals until we meet with it in the lower orders as a bundle of tubes or a simple sac. Yet in all it generates a product which is nearly the same, and which performs the same office throughout. And so of the kidneys, salivary glands, stomach, &c.

So far the analogy is complete between Instinct and its organ and the Principle of Life and all parts of the body which that Principle animates. But Instinct, as we have seen (\$ 1076, a–c), must not, therefore, be confounded with organic products. The analogy, indeed, goes with our other facts in showing that it is the cause of certain results through the instrumentality of the brain, or its equivalent, and the nervous system, as the Principle of Life is the cause of other results in and through that

same system of organs and every other variety of structure.

Coming to the brain of man, the foregoing analogy totally fails as it respects the manifestations of Reason and Instinct. There is an endless variety of the former, but scarcely a real exhibition of the latter. We see all in the structure of the fully developed animal brain that can be detected in the human, or with only the modifications that are incident to approximate species, but a perfect blank as it respects the Rational Faculties. The analogy, however, is complete in man's so far as the brain subserves all that Instinct can discharge among the animal tribes, and all that is relative to the latter in the contributions which the nervous system makes to organic life. The only difference here is the substitution of the Intellectual for the Instinctive functions; and whatever relates to the manifestations of Instinct, and all the influence of the passions upon the organs of organic life, are demonstrative of the co-operation of the brain with the Soul. But the moment we leave this ground, and approach the abstract operations of the higher faculties of the Soul, there is not the slightest indication that the brain has any functional connection with the processes, however much its integrity may be necessary; and the only foundation for the conclusion that such connection exists is the analogy which is supplied by Reason in its exercise of the voluntary and other Instinctive functions of animals (\S 1078 a, &c.).

Again: we have seen that in the infancy of man the Mind is inoperative, while the Instinctive Principle of animals is nearly as active and comprehensive in their earliest as in their latest stage of existence. We have also seen that Instinct is susceptible of artificial impressions, resembling education, in the infancy of animals, and only then. This distinction can proceed only from a radical difference between the Soul and Instinct; and the attendant final causes of that difference consist in the special design of the Soul for Rational functions when the body is sufficiently mature for any practical purposes, and of Instinct for the simple uses of the body. The necessity of Instinct, it may be farther said, is superseded in man not only by the endowments of Reason when it comes into individual operation, but by its delegated offices before its development takes place, while no such protective care, as a general fact, can be extended by the Instinctive Principle to the new-born animal. Hence, therefore, as there are no superfluities in Nature, Instinct is in full operation at the birth of animals, when there is no display of it in the human race, nor is the Soul only slowly developed in its Rational faculties. And thus do the physiological facts, the manifestations of Reason and

of Instinct, and the final causes concur together.

And now comes up the remarkable anatomical fact, which goes also to the same conclusions (although supposed to be in opposition to them), that Instinctive acts are irrespective of the progressive stages of cerebral development, while those of the Human Mind await that development. This corresponds, in respect to animals, exactly with what we know of the general maturity of the functions of all other parts at all stages of life, and with what we have seen of the objects of Instinct and Reason, since the former must be in early operation for the exigencies of Organic Life, while the Soul, in the complexity of its functions, and according to its objects, is only ready to act when the brain shall have acquired sufficient maturity for those endless physical impressions which come through the medium of the senses, and from which the Soul gathers its earliest treasures of knowledge.

Such, then, is the relative aspect in which must be regarded the correspondence between the progressive development and maturity of the brain and the operations of Mind in early life; the development or maturity of the brain having as well a reference to the multifarious physical contributions from the Senses, as to their appropriation by the Soul; while, also, the admirable Design obtains of rendering the brain complete in all its relations to the organs of Organic Life from the moment of birth, and, on the other hand, its endowment for the uses of the Soul exactly progressive with those physical developments of other parts that are indispensable to the objects of Reason at the different stages of advancing life. The Design is inexpressibly sublime in its numerous, yet distinct involutions as they relate to organic and animal life and the uses of Reason. The Soul, therefore, may be, abstractly considered, in

as perfect a state in infancy as at any stage of life.

Thus it appears, that, besides the physical development of the brain which is requisite for the impression of natural objects, that maturity of the organ is, also, as a part of the design, a necessary medium through which the Soul may appropriate the impressions. Having made these advances, the Soul comes to act in more or less independence of sensation, and to multiply knowledge by its own efforts. Nevertheless, it is peculiarly useful to my purposes that aberrations are seen of occasional displays of Reason in early childhood which are surpassed at adult age only by genius of the highest order. In some of these rare instances there had been only the most slender antecedent relative knowledge acquired through the medium of the senses, but the Soul itself originated its own vast conceptions, carried them into a variety of practical applications without the instrumentality of foreign aid, and to an extent where erudition, with all the appliances of sense and the facilities of instruction, falls far short of equal achievements—as witnessed in the institution of mathematical principles and processes. And here we strengthen our position by the converse rule, since in none of the cases has there been a ratio in the advances of Mind corresponding with the advancing maturity of the brain, while in some the early intellectual ability has settled down at adult age to a common mediocrity. In the latter case it cannot be doubted that the progress of the brain has embarrassed the Rational Faculties. Again, there is every gradation in Reason from the Hottentot to the highest order of genius. There are no two individuals alike either in its compass or in the manner of its exercise. How different is all this with Instinct, which directs every individual of every species of animal in one uniform way, and no one of

them enjoys, throughout all generations, any different or greater endowment than all the rest.

And thus do the contrasts between the Soul and Instinctive Principle correspond with the anatomical contrasts, both as they relate to the brain of man and of animals, and to the human brain and other organs in the state of infancy, and with the coincidences in function, instinctive and organic, between the brain of animals or its equivalent and other organs at all stages of life. And here, too, should be brought into review what has been said of the injuries which are inflicted upon the Mind and its associate organ, and through those influences upon the whole organism, by overtasking the Mind in early life, while no such injuries are sustained, but the contrary realized, by a severe exercise of Instinct in the

infancy of animals (§ 563-568).—Note Pp p. 1142.

§ 1078, r. It may be now well to inquire into what is meant by ideas, and whether there be generally any definite conception of their nature, and, by ascertaining the facts, endeavour to show by this method that the earliest acquirements through the instrumentality of the senses demonstrate the self-acting and originating endowment of Mind, and that it is distinguished, at its very dawning, from the Instinctive Principle, by the characteristic of forming ideas of the nature of objects. This inquiry, like the rest, belongs alone to the Physiologist. How, then, does sensation give rise to what are recognized as ideas by Reason? The impressions transmitted to the brain through the organs of sense, or such as may arise from internal causes, do not, certainly, constitute the ideas, as is apt to be supposed; and, according to my demonstration, the impressions made upon the brain cannot, through any physical or chemical influences upon the organ, elicit the ideas from the organ itself. impressions must, therefore, of necessity, call into action a Principle or Agent by which the ideas are alone formed; from which it appears that the process, by which the Mind seizes and appropriates impressions transmitted through the organs of sense, is similar to that by which it multiplies and originates ideas. It is true, animals have the capacity of forming ideas so far as they depend upon the promptings of sensation, and upon impulsive associations with the past that may be awakened by renewed sensations of a more simple nature. But they stop there. They are merely ideas of sensation; while, on the other hand, the results of sensation in man terminate in intellectual images which have no analogies in the brute creation, and these are the essential final cause of the human Soul. It is the Soul, therefore, which, mainly, does the work in acts of intellection, while, in respect to the simple ideas of sensation, external objects, or internal causes like that of hunger, supply the materi-This is enough for my purposes; and it will be as vain to inquire into the modus operandi of the Mind in its abstract operations, or in its perception of external objects, or how impressions are made upon the nerves of sense, or what their nature, or how they are transmitted by the nerves to the brain, or how they call the Mind or Instinct into action, as to interrogate the modus operandi of Creative Energy.

§ 1078, s. In drawing to the close of our subject, we are naturally led to inquire whether there be more than one species of the human race—a

question which is unusually agitated at the present day.

Taking the extremes of the race in physical and intellectual development, it appears to have been definitively shown that there are no anatomical characteristics which distinguish them as different species, but,

on the contrary, mark them as one. All the differences are susceptible of ready explanation through the influences of climate, habits, &c., unless, perhaps, the black color of the African (§ 604-611). The Malpighian rete is abandoned as fallacious, and the color of all the races is now known to depend upon carbonaceous matter deposited upon the surface of the true skin, differing only in degrees of intensity. The greater tint of the Negro has been referred, in a very ingenious Essay by Professor Müller of Brussels, to the hot and arid climate which the darkest of that race inhabit. But, with all his experience in those regions, he is mistaken in his important point that the newborn Negro is white; and his doctrine of the influences of deficient oxygen and dryness of the air in occasioning the deposition and fixedness of the cutaneous carbon is inapplicable to the North American Indian, whose skin is as dark in his extreme Northern as Southern limits; nor has a Northern climate exerted a bleaching effect, in many generations, upon the Negro in America. Müller's theory, therefore, of excess of carbon in the blood from an inadequate supply of oxygen by the rarefied air of the tropics, is invalidated by the exceptions before us. Nevertheless, peculiarities of climate have, doubtless, given rise to all the shades of color, unless that of the Negro form an exception (§ 610). A simultaneous lusus natura of a male and female black, as in the case of the white Negro, may have given origin to the race. (Vide Med. and Physiolog. Comm., vol. ii., p. 640.)

§ 1079, a. Such are the conclusions (§ 1069-1078) to which the evidence of anatomical and physiological facts have successively led; nor have I any doubt that others will see in the demonstrations that man is an animal only in his physical being; that in Mind he is far less allied to the things of the earth than he is to their Author; and will realize a corroboration of their own conceptions, that the Soul and Instinctive Principle are so far differently constituted as implied by the ultimate existence of one in an abstract condition, while the other shares the destiny of organic life. They will see, I say, a new ground of belief in the immortality of the Soul, and in the perishable nature of Instinct. And if this be so, they will see in my premises and conclusions a contradistinction between God and Nature, and what is equivalent to a demonstration of the existence of a Creative Spirit, in which alone the Thinking part of man can have had its origin. And, coming to other details in relation to man, they will realize in the Mosaic declaration that "the Lord God formed man of the dust of the ground, and breathed into his nostrils the breath of life, and man became a living Soul," an Inspiration from Him Who "created man in His Own Image," and repose with equal confidence in the assurance that, although "the dust shall return to the earth as it was, the Spirit shall return unto the God Who gave it." They will abide in the emphatic distinctions between the dust, the breath, and the Soul, and regard the Spirit as a special gift, a new Creation, and the body as referring to materials already in being, and which were designed in their organic state, and kindled into life, to connect the Spiritual part with the material world; and they will also see in the limitation of the statement as to the Soul of man what is the ultimate destiny of Instinct.

Hence it follows, if Revelation be received as to the *immortality* of the Soul and the *death* of Instinct, it must be received, also, as revealing a fundamental distinction between them, and should operate as a perfect barrier with all those who uphold the Scriptures against the common

prejudice of identifying Instinct and Reason, as confounding the revealed distinction, and therefore promoting infidelity in its aim at materialism

and annihilation.—Notes Pr p. 1142, QQ p. 1145.

§ 1079, b. The foregoing subject has been pursued by the Author in a long Article upon "Theoretical Geology," in the "Protestant Episcopal Quarterly Review," New York, April, 1856, in which he has endeavoured to defend, upon scientific, philological, and geological grounds, the literal interpretation of the Mosaic Narratives of Creation and of the Noachian Flood; and, should he think that the spirit of the times will justify the publication of the larger work to which he referred in the original edition of the Essay on the Soul and Instinct, and which is now completed, he will submit it to the press. His main difficulty is the general concurrence of the Religious press in the revolutionary views of Theoretical Geology, though, in saying this, nothing more is intended than a simple representation of the facts. It is doubtful, therefore, whether a hearing can be obtained—certainly not a publisher at his own risk. The Author makes this statement in consideration of his former announcement that such a work was on hand.—See Supplement, p. 923-928, § 1085.

The "Review of Theoretical Geology," to which reference is now made (extending to 120 pages), is an epitome of the larger work, and is believed by the Author, and by better judges, to be incontrovertible. This is said, however, simply for the purpose of inviting a criticism which may either discourage the Author in a farther attempt, or prove to him an incentive to go on with his solitary work. He acknowledges, however, some encouragement in a critical review of Hugh Miller's posthumous work on the "Testimony of the Rocks," which occupies five pages of the Westminster Review for July, 1857, and which is remarkable for its contrast with an otherwise apparently universal shout of applause.*

§ 1080. Again: such is the nature of our premises, that, if the Soul of man be *immaterial*, so is the Instinct of animals. There are, moreover, no violent transitions in nature. The material existences, especially the organic, pass gradually, as it were, into each other. And so, it cannot be doubted, it is with the immaterial, from brute to man, from

man to angels, from angels to God.

"Of systems possible, if 'tis confessed
That Wisdom Infinite must form the best,
Where all must fall or not coherent be,
And all that rises, rise in due degree;
Then, in the scale of reasoning life, 'tis plain,
There must be somewhere such a rank as man;
And all the question (wrangle e'er so long)
Is only this; if God has placed him wrong?"

But we have also seen from our premises that, as soon as Instinct shall have fulfilled its objects, it perishes with the life of the animal; since, especially, all its present uses are limited to the wants of the body. Nor will its extinction affect the analogy of which we predicate its immateriality, nor contradict in the least the immortality of the Soul. We deduce the latter, apart from Revelation, not from the Soul's immateriality, but from some of the facts which contradistinguish it from Instinct, that all its higher faculties have no relation to the uses of the body, and from the analogy which subsists between them and the Attributes of the Creator. We infer, also, the immateriality of the Soul, in part, from the same analogy; though it is essential to this analogy that it be conceded that the Omniscient, Omnipresent, and Omnipotent Being is as different

^{*} A protest against the geological and astronomical perversions of Holy Writ has just been signed (1865) by two hundred eminent scientific men of Great Britain.

from the inert matter of which He is the Author as their manifestations are different from each other. And again, if these premises be admitted, it follows that *immateriality*, or something totally distinct from matter, is indispensable to the unlimited duration of the Almighty, and therefore that it must be rendered equally so to the Soul. But the acknowledgment of a Creator carries with it a full admission of His immateriality, otherwise matter would be self-existent, and God and the Universe would be on common ground. The latter is replete with design, and that is the most that could be affirmed of the former. Neither should depend for its existence upon the other; nor, as we have seen, can matter create matter (§ 14 c). *Materialism*, therefore, is *pantheism—atheism*.

It need not be repeated that the *immateriality* of Instinct is inferred from its feeble analogies to the Soul, though not in the least to any manifestations of those attributes which ally the Soul to its Maker.*

§ 1081. It will have been seen that materialism, in its proper acceptation, and the question as to the materiality of the Soul, are distinct from each other, since the former denies the existence of the Soul as a substantive agent, while the latter admits it. My object has been to substantiate the existence, more than the immateriality of the Soul. But the proof of the latter has constantly attended all that I have shown of the self-acting nature both of the Soul and Instinctive Principle, which contradistinguishes them from every known attribute of matter. The nearest approximation, in the light of analogy, to what may be material, is to be seen in the Principle of Organic Life; and here the resemblance consists in action alone. But the Principle of Life requires the operation of numerous physical causes to bring and maintain it in sensible action. It is impossible, therefore, to adduce a single phenomenon of the Soul or of Instinct that bears a resemblance to the manifestations of matter.

\$ 1082. Our inquiry may be variously pursued, especially upon the great basis of analogy. It is one of no little moment at the present day, and materialism must abide its own facts and method of reasoning; a ground, however, which nothing can shake when presented according to its ordination in nature. In the present case, the admitted facts are co-extensive with all animal existences, and they are bound together in the different races by close resemblances. Indeed, in each of the series the facts differ only by shades. The evidence here is of the strongest possible nature, not only on account of the universality of the facts, but because they are founded in the unchanging character of organic beings.

Resting, therefore, in the conclusions which I have now expressed, and anxious for their greater prevalence against a progressive and already widespread materialism, I have been led into this discussion in the hope that it may remove some of the obscurities of the subject, and also advance the great truths in Physiology and Medicine. The province of the Physiologist extends beyond the mere physical relations of matter and Mind. Of those relations he is the only expounder. But it devolves upon him, also, to seek in the depths of Physiology for the constitution of Mind as distinguished from matter; and thus, also, contribute towards a right faith in a future state of being. Wherever, indeed,

^{*} We have seen, § 168, that Professor Müller, in discussing the nature of the Vital Principle, concedes that even this may be an immaterial substance, and that "there is nothing in the facts of natural science which argues against its possibility, and its independence of matter, though its powers be manifested in organic bodies—in matter."

he turns his inquiries into organic nature, he sees in the mechanism of every part—individually and collectively as a harmonious whole—in every function and product, separately and relatively—in the properties by which they are carried on, and in the laws by which they are governed, the most perfect evidences of consummate Design. It is the duty of the Physiologist to turn all this immense weight of proof against those crude doctrines of materialism, mental and medical, which have had their origin either in the closet of the speculatist or in the laboratory of the Organic Chemist. And thus, also, shall he secure from Mankind that homage for Medicine which is due to "the Divine Art," and again restore the Hippocratic axiom that "a philosophical physician is like a god" (§ 235).

§ 1083. Before concluding our subject I shall avail myself of the proof which it supplies against the doctrine of spontaneity of living beings, now extensively prevalent in the scientific world, and against which I have alleged many objections in the Medical and Physiological Commentaries (vol. ii., p. 123–140), and again in the original Essay on the "Soul and Instinct," and in that upon "Theoretical Geology" (§ 1079, b),

and in these *Institutes* (§ 14 c, 170, $350\frac{3}{4}$ a-m).

As it respects the Soul and Instinctive Principle, we have now seen that they are substantive existences, and all organic beings are made up of the common elements of matter. But there is no element known in the inorganic kingdom which affords any of the manifestations which characterize the Soul and Instinct, or any of the results of the organic mechanism. The latter, therefore, was endowed with new properties when the elements were brought into organic union. To say that such properties were "slumbering in the elements," is a frivolous assumption (§ 14 c, 175 d, $250\frac{3}{4}$ b, c, f-k), and necessarily involves the conclusion (which has been probably intended) that the Soul, also, is equally inherent in the elements, which is the worst kind of materialism. But the manifestations of the Soul and Instinct are, as we have seen, not only totally different from those of every organic process, but cannot be generated by the material part. These principles, therefore, were as much created as the elements of matter, and, as they exist in union with the organized structure of man and animals, it is inferable that the structure was created simultaneously, and by a common act, with the spiritual part. Or, if the material elements were first combined, it would equally follow that it was a direct Creative Act, since the Soul and Instinctive Principle must have been created for the distinct purpose of being associated with the material body. The rule, of course, applies, through the analogies of structure, to the vegetable kingdom, and which it is equally consistent to suppose was created in the form of plants as of seeds, or as that man and mammiferous animals were created in a state of maturity, according to my demonstration in the Essay on the "Soul and Instinct" (p. 158-173).—Note Pp p. 1142.

I have also said in relation to the common opinion that intestinal worms are of spontaneous origin, that, if this be admitted, it must be also conceded by all that is sound in analogy, that the door is equally open for any other animal, and for man himself. The hypothesis is without a plausible fact, while the ova of these parasites, and of such as are found in the organization of the body, even in the fœtus, may require, in the natural external condition of the animals, a magnifying power of some hundreds of times to render them visible. They may, therefore,

be absorbed into the circulation, where their new mode of existence, as well as in the intestinal canal, may so modify the condition of the animals that they shall lose all resemblance to their characteristics in the external world. The animal and vegetable tribes abound with equally remarkable aberrations, that arise from climate, domestication, and cultivation alone. But more than this. From whence comes the elaborate organization of these so-called parasites and their wonderful systems of Design? How and from whence do they obtain, at their start into being, the seventeen or eighteen elements of which they are composed, and which are indispensable, in every species of animal and plant, to the beginning of existence? And should not this objection have been urged against the pretended creation of the Acarus Crossii out of a simple solution of silex in water ($\S 350\frac{3}{4}$, h)? Is there any thing in Chemistry that will expound the intimate union of such a number of elements into compounds of the most exact nature, or these compounds, by any thing known in physics, into systems of Design, and this for every species of animal and plant, if you had all the elements to begin with? Or, take oxygen, hydrogen, nitrogen, and carbon alone, the Chemist completely fails to fabricate the most simple organic compound (§ 350, No. 39, parallel columns). But by no possible contingency can the seventeen or eighteen elements have been assembled for a single individual plant or animal; and when all the species are regarded collectively, the supposition becomes palpably absurd. Nothing but Creative Power could have gathered them together in a single instance. This disposes, also, of the "parturient faculty of the earth," as it is called in the "progressive development" system of theoretical Geology. Nor can the pretence be set up that the so-called intestinal parasites grow out of a previously organized part, for they are perfectly independent beings, and have no attachments to the intestine. Or, if attachments exist in other cases, they are precisely upon common ground with parasite plants as it respects their original independence. The doctrine which ascribes Muquet "to the production of a parasite plant within the epithelial cell" is open to the same objections as apply to the spontaneity of animals, and is contradicted by all the physiological, pathological, and therapeutical facts. It is alone worthy of the most imaginative of the microscopical school, setting aside its pernicious tendencies in Religion* (Continued in § 1085.)

I can not but think, after all, that whoever regards the animalcule, that can be discerned only through a high magnifying power, in all its wonderful complexity of organization, seemingly existing in nothing, in all its close analogies in composition and structure to man himself, and often with a large development of the Instinctive Principle, and ponders upon the same analogies as they are only less complex in worms, and only still less in parasitic plants, and considers the stupendous Designs which each part, and all together in unison, fulfil for the growth and well-being of each individual, and how there is no deviation in structure and functions among all the individuals of the species respectively, must concede the descent of the whole from progenitors that had been brought into being by an Intelligence higher than that which is enabled to explore the labyrinth and trace out the Designs (§ 1051), and that thus informed, he must bow with reverential awe under the inspiration of such contemplations. (See Index I., Article Design.)

^{*} The Author is gratified to observe that the spirit of his arguments upon spontaneous generation, as expressed here and elsewhere, is adopted in Amer. Jour. of Science and Art, May, 1859, and by the same writer as referred to in note at p. 196, § 360. Comptes Rendus, 1859, contains conclusive experiments in favor of CREATIVE FOWER.—1860.—Notes Pp p. 1142, Qq p. 1145.

THE RIGHTS OF AUTHORS.

§ 1084. Upon all questions of priority that concern the advancement of Science and Art, there is, doubtless, a general understanding that the principle should not only be sacredly observed, but that, whenever violated, there should be a common effort to repair the injury. This is alike due to the individual, to the principle, and to the common good. Nor is it less the privilege of the individual, who may have good reason to think that the principle has not been extended to himself, to vindicate his rights, and to appeal to that sympathy which forms the bond of union among honourable men. It is a common cause, and not seldom demands

protection.

The Author of these Institutes (and it will soon appear that he acted wisely) has sometimes thought it expedient to assert his claim of originality, in advance, to many doctrines promulgated in the work; as, for example, all that is most essential in the application of the Nervous Power, or Reflex action of the nervous system to Pathology and Therapeutics, and to much of what is most important in the natural state of the functions. This may be readily seen by consulting p. 106, § 222 b, p. 107-116, § 224-234, p. 295-318, § $475\frac{1}{2}$ -493 d, p. 321-341, § 495-514, p. 343-353, § 516-524, p. 465-467, § 714-719, p. 506, § 803-804, p. 515–516, § 819 b, p. 661–663, § 894–896, p. 666–676, § 902 b–904, p. 679–680, § 905 a, p. 690–691, § 906 g, p. 693–695, § 917–923, p. 698, § 931–935, p. 703–711, § 940–952, p. 745, § 990 $\frac{1}{2}a,b,&c.$, where all the subjects relate to the reflex action of the nervous system, and present the nervous power as an important vital agent in the various processes of organic and animal life, in the production of disease, in the operation of remedies, in all the results of bloodletting, in the changes which take place in the secreted and excreted products—having also originally set forth the agency of the nervous power in voluntary motion (INDEXES, Article Will), and as this power is the efficient cause of the modifications of organic results under the influence of mental emotions (INDEX II., Article Mental Emotions, and references at p. 867, § 1067). Indeed, as the reader will have seen, the foregoing doctrines relative to the reflex action of the nervous power, operating as a vital stimulus, or vital depressant, or vital alterative, as it may be modified in its nature by one cause or another (§ 226-232, 481, 500, $891\frac{1}{2}k$, 894b, $990\frac{1}{3}a$, b), pervade this work. The same doctrines are at the foundation of the Author's "Medical and Physiological Commentaries," published in 1840, while the present work was published in 1847. In the mean time he has also laboured to inculcate them throughout his course of Medical Lectures in the University of New York-first on the Institutes of Medicine and Materia Medica from the year 1841 to 1850, and subsequently, to the present time (1857), on General Therapeutics and Materia Medica.

It may be worth saying, also, that the Author preserves the term "sympathy," though always meaning by it, as he strictly defines, reflex action of the nervous system, and this whether he employs the term "remote sympathy" or "contiguous sympathy." The elements of sympathy, as set forth in the work, are the nervous power and sensibility. All

this will be readily seen by a reference to INDEXES. Also, among other general remarks of a similar import, the Author has the following:

"Notwithstanding all the laws of sympathy that are necessary to the full interpretation of the remote effects of morbific and remedial agents are as well established as any laws in physics, they have not been applied to these important objects; but, on the contrary, those philosophers who have contributed most to their critical exposition, overlook their pathological and therapeutical bearings, and cling to the doctrines of humoralism and of the operation of remedies by absorption; nor have they applied, in the least, the nervous power in a philosophical manner to an explanation of the natural phenomena of sympathy" (p. 111, § 234 a, 169 e 435 c, 906 g).

When the foregoing works were first published, it was in the midst of a universal prevalence of the chemical and physical doctrines of life and disease, and the Author stood alone in the field of Vital Physiology, and in the application of the reflex action of the nervous system in resolving the great problems in Physiology, Pathology, and Therapeutics. A few, however, had the quick sagacity to see its importance as presented by the Author; and since the decline of Organic Chemistry began, others have entered upon the inquiry, and the most zealous have promulgated as original with themselves many of the doctrines which belong to the Author of these Institutes, especially such as are relative to the nervous system. But the Author has relied upon his professional brethren for ultimate justice: "Ultimum et unicum remedium." "Jus aliquando dormitur, moritur nunquam."

But the Author has lately seen so great an indisposition, in certain quarters, to allow him any credit for his labours, that he has concluded to make this expostulation, which refers, particularly, to the following dispute about the authorship of matters in which neither of the gentlemen has any interest, but the writer alone of these Institutes. This rival claim appears in an Article published by J. Adams Allen, A.M., M.D., in the "Medical Independent" for September, 1857, p. 381, Detroit, Mich-

igan. Thus:

"It appears from a late number of the London Lancet that M. Hall (Marshall Hall) recognizes to a certain extent the priority of Dr. Camp-

bell. His words are these:

"'I arrive at this conclusion: the idea and the designation of an excito-secretory action belongs to Dr. Campbell, and his details are limited to pathology and observation. The elaborate experimental demonstration of reflex excito-secretory action is the result of the experimental labors of M. Claude Bernard. My own claim is of a very different character, and I renounce every other. It consists in the vast generalization of excito-motory action throughout the system. I trust Dr. Campbell will be satisfied with my adjudication. There is the excito-secretory function as applied to pathology, an ample field of inquiry for his life's career, and it is indisputably—ms own. He first detected it, gave it its designation, and saw its vast importance."

Dr. Allen then continues:

"M. Hall thus far freely and fully admits the priority of Dr. Campbell, and the latter gentleman bases his claim upon the date, May, 1850. I shall undertake to show that this same doctrine was first publicly announced and illustrated in my Lectures at the Indiana Medical College in November, 1848, and thenceforth continuously during the continuance of my public teaching before the several classes of that College,

and also the Medical Classes of the University of Michigan until my connection with that Institution 'expired by limitation' in 1854. My own manuscript containing this doctrine was written in May or June, 1848"—that is to say, more than one year after the publication of these Institutes.

"What I do claim is the great generalization that the excito-influence is followed by a reflex change in which the effect is NOT A MODIFICATION OF VASCULAR AND NUTRIENT ACTION. That this effect takes place by Means of the double nervous arc. A vast number of therapeutic phenomena are thus explained." I preserve in the quotations Dr. A.'s capitals and italics.

Now the whole of the fe

Now the whole of the foregoing doctrine is impressed upon the *Med. and Physiolog. Commentaries*, and upon more than half of the pages of these Institutes, and has been always taught extensively in the Author's Lectures since 1841. In respect to the present work, see, particularly, pages 106 to 111, 283 to 362, and the chapters upon *Remedial Action, Therapeutics, Counter-Irritation, Cathartics, Se*

cretion, and Excretion, INDEX II.

Dr. Allen claims, also, the application of the principle to Therapeutics, and remarks that "in my course upon 'General Therapeutics' the subject of 'Counter-Irritation' came under review," and concludes that "the impression must be transmitted to the nervous centres, and thence reflected to the affected organ. In other words, the influence is primarily exerted upon the cerebro-spinal system, and secondarily upon the internal affected organ. This is the gist of the whole matter, and the point consists in the recognition of reflex cerebro-spinal action, which, in the instances adduced, give rise to a molecular or integral change in the inflamed tissue, and not a muscular contraction. The oral elaboration of this principle was suggested by an idea [?] which does not even now appear to have occurred to either M. Hall or Dr. Campbell, viz.: The motor effect is merely secondary, and not a necessary part of the action of the nervous arc."

Here, also, the whole of the foregoing doctrine appears throughout these Institutes, but not to the neglect of the *sympathetic nerve*. In the long chapter upon "Counter-Irritation" it will be seen that the Author has employed nearly the language of Dr. Allen, as also in that upon "Remedial Action," with a great elaboration and extensive application of the doctrine throughout the work; which had been also antecedently taught in his Lectures for seven consecutive years before Dr. Allen promulgated the same views. (Indexes, Reflex Action, Nervous Power).

To show still farther this partiality for the Author's Writings, or his Lectures (then familiar to his large classes of students), he will quote from Dr. Allen the following conclusions, which he also places in capitals:

- "THE EFFECT IS MOTORY, IF CONTRACTILE FIBRE BE PRESENT.
 "THE EFFECT IS SECRETORY, IF SECRETORY ORGANS BE SUPPLIED.
- "THE EFFECT IS SENSATION, IF SENSITIVE NEURINE BE REACHED.
- "The effect is perception, or intellection, if the organ thereof be in connection with the reflex nerve."
- "The effect produced, then, depends upon the STRUCTURE AND CONDITION of the organ reached."

"This influence is not confined to the mere increase of action, as the term excitor might perhaps suggest. The reverse may take place—the excitor may rather become the depressor. It would be as correct to say the depressor-motory, the depressor-secretory, as to say the excitor-idem."

Now the Author of these Institutes not only dwells emphatically upon the depressing and sedative influence of reflex nervous action, according to

the nature of the remote causes and special conditions of disease (§ 224- $233\frac{3}{4}$, 234 d, 455 d-f, 481, $488\frac{1}{2}$, 500 c, ee, 503, 514 b-h, 516 d, no. 13, $526 d, 847 g, 863 d, 891 \frac{1}{2} k, 894 - 895, 902 b - m, 904 a, 945, 947, 951 c,$ 966, 973-976, $990\frac{1}{2}a$, b), and upon its operation according to the natural structure and special vital constitution of organs, and their varying conditions (p. 59, \S 129 g–i, p. 61–69, \S 132–15 $\tilde{6}$, p. 73, \S 163, p. 109, \S 229, p. 111, \S 233 $\frac{3}{4}$, p. 285, \S 455 d–f, p. 313, \S 487 h, p. 353–362, \S 525–529, p. 374–383, § 576–584, p. 415–417, § 649, p. 418, § 651 b, p. 421–423, § 657–658, p. 523, § 827 c, p. 542, § 854 bb, p. 613, § 892½ b, p. 644–650, \$893 c-i, p. 665-672, \$902-903 b, p. 746, $\$990 \frac{1}{2} b$, and the numerous references in those sections); but the Author represents, also, the reflex action as variously alterative in organic life, and this imputed attribute pervades the Author's writings. He enforces, everywhere, the doctrine that the reflex action of the nervous power is the modifying cause through which all the changes are effected by morbific and remedial agents in parts that are not immediately connected with the direct seat of their action; and, farther, that the principle is precisely the same when the nervous power is brought into operation by direct influences upon the nervous centres (as in the case of their diseases, or when the Passions operate, or as the Will determines voluntary motion), as it is when it is brought into operation in that indirect manner known as reflex action. Hence he has called the former direct nervous action.

Indeed, every one of the foregoing doctrines, in all their particularities, as quoted from the American Claimant, are taught, at great extent, in the volume before us, as may be readily seen by consulting the references made in this protest, and, more extensively, Indexes, Articles Structure, Nervous Power, Sensation, Sensibility, Sympathy, Organic Functions, Remedial Action, Mind, Mental Emotions, Will.—"Si quæris monumentum, circumspice." It may appear superfluous, however, to have made these specific references in an article connected with the work itself; but it is done to encourage those readers who might not otherwise be inclined to ascertain the facts.

But the writer is more interested with the European Umpire, of

whom he has felt that he has much more reason to complain.

"Omne animi vitium tanto conspectus in se Crimen habet, quanto major, qui peccat, habetur."—JUVENAL.

That the Author's physiological and medical writings were generally known in Europe many years before the period at which "Dr. Campbell bases his claim" (1850), is evident from the distinguished honors to which they had led in that Country before that period-that from the Medical Society of Prussia as early as 1842—that from the Medical Society of Leipsic in 1843; and the "Medical and Physiological Commentaries" (of 1840) were published simultaneously in London and New York; and as to the United States, the Commentaries were early distributed throughout the land, and his Institutes of Medicine more than a year, also, before Dr. A.'s Lectures were delivered; and the Author's Lectures at the University, which form the groundwork of his Institutes, had been listened to annually by Medical Students from all quarters of the Union since the year 1841. In 1848 the Author applied the doctrine of reflex nervous action to a physiological demonstration of the substantive existence of the Soul and Instinctive Principle, which was then published in pamphlet form, and in 1849 the work was extended and assumed the shape of a book, and is now incorporated, in its essential parts, in these Institutes. Also, fully, in Author's Materia Medica, 1848, p. 176-180.

Nor is that all; for the whole of this doctrine of reflex nervous action, and of the operation of the nervous power as an alterative, an excitant of the secretions and of vascular action (both direct and reflex), a depressant and sedative (according to the nature of exciting causes), and the great immediate cause of diseases and their cure—variously modifying organic actions—was set forth extensively and circumstantially in an "Essay on the Modus Operandi of Remedies" in 1842, of which the Author distributed, at that time, a large number of copies in London, and addressed four thousand copies to Physicians throughout the United States. Author not only sent a copy of the work to Dr. Hall, but dedicated it to him (along with Prof. J. Müller and Dr. A. P. W. Philip) in connection with an "Essay on the Philosophy of Vitality;" and he may add that he controverted, in the former Essay, doctrines of Dr. Hall (in "Memoir on Diseases and Derangements of the Nervous System, 1841"), which were in direct opposition to those which are now in question (also, p. 296-297, § 476½, b). These Essays were subsequently bound up in the Third volume of the "Medical and Physiological Commentaries," where the former may be readily consulted. But Dr. Philip had fully deduced from his experiments the sedative as well as exciting influence of the nervous system upon vascular action before Dr. Hall's experiments were made (§ 492)—See Index II.—HALL, M.—for many other unpardonable criticisms.

As to M. Bernard, his experiments bearing upon the connection of the nerves with the function of secretion, however much they may have been varied and multiplied, were anticipated long before by those of A. P. W. Philip, which are quoted extensively in these Institutes (p. 290-321), and towards which Dr. Hall had no friendly disposition (p. 306-308, and where the writer has controverted his views). The merit of originality which belongs to the present writer, in relation to these experiments, consists in their extensive application in illustrating the functions of the nervous power as a vital agent, profoundly interested not only as an "excito-secretory" power, and as a modifying cause of all secreted products, nutrition, &c., when diverted from their natural standard, but in deducing from them a universal agency of the reflex action of the nervous system, through "the double nervous arc," in the production and cure of disease, and by which he laboured to explode the chemical and physical doctrines as early as 1840. But, that the writer may not be misapprehended, he will say that he endeavours to establish the fact that secretion in animals, as in plants, is conducted by powers implanted in every part, but that it is constantly influenced physiologically, pathologically, and therapeutically, by reflex action of the nervous system, as also by direct action (§ 227, 481).

The writer is very sensible that unaccountable coincidences often present themselves in the development of new thoughts, and in the discovery of hidden things, especially where enduring reputation may be won. "Ubi mel, ibi apes."—"Uno tiene la fama, y otro carda la lana." But the reader, with these Institutes before him, will quickly find that much that is claimed by Dr. Hall, and all that he has granted to Dr. Campbell, in the foregoing quotation, and, therefore, all that Dr. Allen appropriates to himself,* abounds in this volume, and, in fact, constitutes the life and

soul (" $\zeta\omega\eta$ καὶ ψυχή") of the work, as it does, also, of the "Commentaries," and of the Essay on the "Modus Operandi of Remedies;" nor can the reader fail of the conclusion that, were Dr. Hall's "adjudication," and Dr. Allen's after-thought, founded in any justice, and were not the claimants themselves the obnoxious parties, the present writer would have been long ago convicted by them and by others of arrogant assurance and the grossest plagiarisms. Nevertheless, the Author is most happy to find that his solitary position is becoming relieved, and that a practical direction has been given to his labours by others which cannot fail of carrying forward the great doctrines at which he has toiled, and against manifold obstacles, during his professional life.—Note X p. 1127.

New York, September, 1857.

Postscript.—From what has been seen in the last preceding Article (which was at first intended for publication without this Postscript), it will not appear remarkable that the Author regards it as a duty to himself and to the cause of that Philosophy in Physiology and other branches of Medicine which he has labored to introduce, that he should set forth the principal details of what he considers himself the unquestionable Author. Prompted, therefore, by these and other obvious rea-

sons, he proceeds to assert his claim of originality to-

1. All that is relative, in principle, to Reflex Action of the Nervous System in Pathology and Therapeutics, including the application of antecedent experiments to determine the "Laws of Sympathy" and of the "Vital Functions," as they respect the natural conditions, to all the great problems in those branches of Medicine, so far as the Nervous Influence is involved as a modifying cause; and a systematic generalization of the whole subject. The Laws of Reflex Action of the Nervous System, in their Physiological aspect, were understood, to a large extent, as early as the time of Prochaska (§ 463 b, 476 b), and justice demands of us that analogous contributions by Hippocrates shall be acknowledged (§ 463 a), while, also, it will be seen through the foregoing references that this most important subject, in philosophical and practical medicine, had engaged the diligent attention of other eminent observers prior to the grand discovery by Sir Charles Bell of the anatomical media (§ 464, &c.), by the aid of which, and the labors of many others, the great Prussian Physiologist reduced the laws of reflex action of the nervous system to a masterly generalization. The Author of these Institutes had also given his critical attention to the researches of Marshall Hall, and has expressed his opinion of their merits in many places, and summarily in § 463 b.

2. The doctrine of Modification of the Nervous Power by the Causes which bring it into action, and according to the nature of each Cause, whether mental or physical, remedial or morbific, external and internal, and through which its Alterative influences are exerted in conformity with its various modifications, respectively—regarding, therefore, the Nervous Power as a Vital Alterative Agent and susceptible of an endless variety of changes in kind from the influence of exciting causes; being thus rendered, in its extremes of change, either a vital stimulant or sedative, exerting alterative effects, with corresponding results in both the solids and fluids.—The application of this philosophy equally to the cure and production of diseases in all their gradations. (INDEX I. and II.)

3. The doctrine and demonstration of the operation of Remedial Agents and Morbific Causes by Reflex Action of the Nervous System, as, also,

through the foregoing modification of the Nervous Power (No. 2), and all that is relative to the same action in Pathology and Therapeutics.

4. A distinct exposition of the modus operandi of Counter-Irritants through Reflex Action of the Nervous System, and their associate local influences; exemplifying, also, by these agents, the modus operandi of all other agents applied to the skin when they produce constitutional, or any internal effects, whether remedial or morbific—as in the case of cold, mercury, &c. (Index II., Counter-Irritants; Causes, Morbific; and Remedies).

- 5. A distinct exposition of the modus operandi of the Seton through Reflex Nervous Action and local organic influences, as exemplifying all the essential philosophy that is ever concerned in the operation of all remedial and morbific agents, as set forth in the Author's Essay on the Modus Operandi of Remedies (1842), and in these Institutes (p. 679–681, § 905 a) -being, however, only parallel with the author's demonstration of the operation of Blisters and other Counter-Irritants through the same causations.
- 6. The operation of Anasthetics through Reflex Nervous Action, as contained in this work.
- 7. Distinction between the agencies of Reflex Nervous Action in the modus operandi of the Author's group of Alteratives and among other denominations of Remedies (INDEX I. and II.)—an important consideration, by which the gradual operation of Remedies through Reflex Nervous Action is rendered clearly intelligible, as in the progressive influences of small and frequently repeated doses of tartarized antimony, mercury, &c. (p. 344-345, § 516 d, No. 6, 889 m, 902 i-m, 904 bb). And so, also, of the progressive operation of Morbific Causes, either physical or mentalas in hydrophobia, sympathetic diseases, &c. (p. 421-422, § 657 a, b, p. 465-466, § 715, p. 661-663, § 894-896). The example of the Seton illustrates the principle (No. 5).

8. All embraced in this work, and in the Medical and Physiological Commentaries (vol. i., p. 124-384) upon the Influences and Modus Operandi of Loss of Blood (whether in General Bloodletting or Leeching), which are interpreted by the Author upon purely Physiological Laws.

and mainly through Reflex Action of the Nervous System.

9. The Law of Adaptation, operating through Reflex Nervous Action

(INDEX I.).

10. The philosophy of the natural operation of the Will and Mental Emotions through the direct development and action of the Nervous Power, and its effects as an Alterative agent when the latter operates in the cure or production of disease, as embraced in this work.

11. Demonstration of the direct development and propagation of the Nervous Power as an Alterative agent, or a simple Stimulant or Depressant, in diseases of the nervous centres, &c., and as concerned in Loss of Blood

along with Reflex Action, &c.

12. What is relative, in this work, to peculiarities of Structure in its Vital constitution in different parts (p. 50-73, &c.), and their important bearings upon Physiological, Pathological, and Therapeutical doctrines, as it relates both to the direct action of remedial and morbific causes, and their operation through Reflex Action of the Nervous System.

13. The proof and reasoning embraced in these Institutes, and in the Medical and Physiological Commentaries, and other works, in behalf of VITAL SOLIDISM, as applied to Physiology, Pathology, and Therapeutics,

and in opposition to the Chemical hypotheses.

14. Special deduction of *Vital Principle*, and peculiar Laws of Organic Beings, from their *Composition*, as embraced in this work (p. 23-49).

15. Special deductions from *Nitrogen Gas*, as contradistinguishing the Organic from the Inorganic Kingdom, as contained in the Essay on the Philosophy of Vitality (1842), and briefly in this work (p. 34-36, $62 \ a-k$).

16. Special deduction of the principles of *Vital Solidism*, Physiological and Pathological, from the development of the incubated *Egg* and the physiology of *Generation*, as contained in the Essay on the Philosophy of Vitality, and in these Institutes (p. 36–49, \$ 63–81).

17. Analysis and elaboration of the Properties of Life, as contained in

this work (p. 73-125).

18. The proof adduced in this work, and in the Medical and Physiological Commentaries (vol. i., p. 1–119), of the existence and office of the *Vital Powers* or *Vital Properties*, with a disproof in the latter work of the supposed identity of the Nervous Power and Galvanism, with the variety of proof herein contained of the wonderful attributes of the Nervous Power, as one of the properties of the Vital Principle of Animals.

19. Exposition of Law of Vital Habit (p. 363-370, § 535-537).

20. All embraced in these Institutes and the Medical and Physiological Commentaries in disproof of the Chemical and Physical hypotheses as applied to Physiology, Pathology, and Therapeutics.

21. All herein and in the Medical and Physiological Commentaries

(vol. i., p. 385-712) in refutation of the Humoral Pathology.

22. Demonstration of the dependence of *Digestion* upon Vital Laws, and to the exclusion of the Chemical, as contained in this work and in the Medical and Physiological Commentaries (vol. ii., p. 79–122).

23. Demonstration embraced in these Institutes, and in the Medical and Physiological Commentaries (vol. ii., p. 1–78), of the dependence of *Vegetable* and *Animal Heat* upon Vital Laws, and against the Chemical hypotheses.(p. 236, § 435 b).

24. Experiments relative to the Circulation in the Brain, showing that

the organ is depleted in Bloodletting (p. 824–828).

25. Demonstration of the dependence of Absorption and Circulation in Plants and Animals upon Vital Laws (p. 817-824, § 1053-1055, and passim).

26. Much of what herein relates to the Powers which circulate the Blood, and in the Medical and Physiological Commentaries (vol. ii., p.

398-426).

27. The distinction between *Inflammation* and *Fever*, and what is most essential in proving an active condition of the immediate instruments of Inflammation, and the dependence of its different stages, and of all its phases and products upon Vital Laws, as embraced in these Institutes, and in the Medical and Physiological Commentaries (vol. ii., p. 141–214).

28. All herein relative to the philosophy of *Venous Congestion* and *Varix*, and in Medical and Physiological Commentaries (showing that *venous inflammation* is the pathological condition), and the proof of the dependence of *Tubercle* and *Scrofula* upon Inflammation, and *Cold* as a cause of Congestion, &c., in the several Appendixes to Venous Congestion in Commentaries (vol. ii., p. 215-640).

29. Much of the Physiological bearing of organic changes incident to different periods of Life upon practical medicine (p. 373-383, § 570-

584).

30. The uses and abuses of *Morbid Anatomy* as contained in this work and in Medical and Physiological Commentaries (vol. ii., p. 641-677).

31. A generalization of the mutability of the Properties of Life, as lying at the foundation of disease and of its cure, and of many natural changes of organization at the different stages of life, of gestation, lactation, &c. Also, the doctrine of a substitution of pathological conditions by Remedial Agents, through reflex nervous action, more favourable to the law of recuperation than such as had been impressed by the truly morbific causes, and their progressive nature; and the physiological distinction which the Author has drawn between remedial and morbific agents.—See Index I., VITAL PROPERTIES.—Index II., REMEDIES; CAUSES, MORBIFIC; THERAPEUTICS.

32. The demonstration of the operation of Astringents upon Vital Prin-

ciples, and through reflex action of the nervous system (p. 370-378).

33. The demonstration of the operation of *Tonics* upon Vital Principles, and through *reflex action of the nervous system* (p. 579-583, § 890½, p. 676-679, § 904 c, d).

34. Attempted refutation of *Theoretical Geology*, and of *Spontaneity of Being*, to which there are references at p. 908, § 1079 b, p. 910-911,

§ 1083.

35. A critical exposure of the fallacies of the Medical Doctrines embraced in the Writings of P. Ch. A. Louis, in Medical and Physiological Commentaries (vol. ii., p. 679–815, and passim).

36. A critical exposure of the fallacies contained in the WRITINGS of LIEBIG, so far as he has applied Organic Chemistry to Physiology, Pathology, and Therapeutics (p. 147–178, p. 234–279, and passim).

37. A Therapeutical Arrangement of the Materia Medica upon Physiological principles, and in the order of the relative therapeutical value of the different substances, and as applied to particular forms of disease.

38. All that is relative to the Substantive Existence and Physiology of the Soul and Instinctive Principle, as embraced in this work, and in the former Essay upon those subjects (See Index II, *Note* at p. 873).

39. Opinion that the Will exercises a controlling influence upon the Intestine in Defecation, and as evincing a remarkable instance of Creative Design, p. 325, § 500, e.

Note.—The foregoing specifications appeared in the Fourth Edition of this work, and as the Author has seen no objections alleged that invalidate any of the claims, but rather a general, or at least tacit, admission of them, and as they have been spontaneously republished in several medical periodicals, he leaves them in this Eighth Edition without modification, but will add that, in regard to the term "excito-secretory function," although an unimportant matter, and referring simply to the physiological condition, he suggested the term itself in sections 514 h, 512, 902 q, and in many other places; nor will he neglect saying in this connexion that he attempted to show the influence of the sympathetic nerve upon the action of the blood-vessels, and the operation of Counter-Irritants and of Leeching through reflex nervous action as early as the year 1834, in an article in the London Medico-Chirurgical Review. 827, § 1056. The author has now taught the doctrines of these Institutes in the Medical Department of the University of the City of New York for twenty-six years.

NEW YORK, 1867.

SUPPLEMENT.

[The first paragraph of the section with which this Supplement begins appeared in the Fourth Edition. All that follows belongs to the Fifth.]

CORRELATION OF FORCES.

§ 1085. An important omission was made in that part of our Appendix which relates to the progress of "physiological and pathological chemistry" (p. 779) in not having converted to our purposes the doctrine of the "correlation of forces," to which organic chemistry, in its discomfiture, is now appealing.* This fiction is equivalent to an abandonment of the whole ground to the vital solidist. It is a full acknowledgment that the powers of nature, as they operate in the inorganic world, are entirely inapplicable to living beings, and that the assumption has become necessary that they are transmuted into something very different, but wanting in every other shadow of proof than such as rests upon mere analogies observed in the inorganic world, and without any analogies between organic and inorganic beings. The supposed transmutation is therefore claimed by the vital solidist as his vital principle. But, curiously enough, the chemico-vitalist, in accepting this assumption, contends, also, for a vital principle. nally, if the vital force be a "transformation of heat," electricity, &c., why is heat, electricity, &c., so conspicuously manifested as such in living beings? Why not altogether converted into the supposed "correlated force?" How will be reconciled with the supposed "metamorphosis of heat into vital force" the prodigious elaboration of absolute heat by that organic structure which is said to be the medium through which "heat is transformed into vital force?" Strange function this, which is simultaneously engaged in "transforming heat into vital force" and generating heat under its usual conditions! We suppose that it will scarcely be contended that this sensible caloric is also vital force, notwithstanding its complete submission to the vitalizing power of the whole organic being; or, if this consistency be maintained, the manifestations, by this product of organization, of all the usual effects of caloric, both upon dead and living matter, equally consign the speculation to the same fate as is attending the physical forces in their less mystified application to the science of life ($\sqrt[6]{234}$ g, h, 350, nos. 16, 17, 19, 20, 21, 37, $376\frac{1}{2}$, $447\frac{1}{2}$, 448).

On different occasions, and sometimes in the course of this work (p. 180–190, § 350\(\frac{2}{3}\) e-m, p. 910–911, §1083), I have shown that it is the tendency of this generalization of organic and inorganic nature to lead to other violations of fundamental laws, of which one of the most glaring is the doctrine of the spontaneity of living beings, and, therefore, a fully implied denial of a Creative Power—by which I mean a Power totally distinct from nature. The latter, it is true, is often obtruding itself under the name of the former; and this, I apprehend, is what is intended to be implied by the common geolog-

* There are other arguments upon this subject in my "Examination of Reviews," and in "Notices of Reviews" (1841), since bound up in Med. and Phys. Comm., vol. iii. Much of the present work is against the doctrine of "Correlation of Forces."

ical expressions, "the developmental system," and "the progressive development" of living beings, according to their rank in the scale of organization. Sometimes, indeed, this appears to be distinctly avowed, and of which I shall present an example from a late geological work of good repute to show the method in which the doctrine of *chance* is tricked out with the devices of "positive science," but in opposition to its

plainest facts and principles. Thus, it is said that,

"We are not told that the parturitive powers of the earth, when they first began to be exercised, were very different from what they are now. They may have been more rapid or more slow, but if it was a real physical energy, governed by law, and not merely an arbitrary sign of a contra-natural power, it must, at least, have had a harmony in its workings—such a harmony as would have required that the widely varying among its diversified effects should bear some ratio to the greater strength or longer duration in the cause. It would not have brought out the full-formed, full-grown, and ripened cedar of Lebanon in the same time it required for giving birth to the mushroom. No intimation is given that the first growth, after the instantaneous starting power, or the utterance of the creative Word, was not as natural as any that followed. We are rather led to believe that this first growth gave the law to all subsequent production. If the first plants or trees did not come from a previous organized seed, the first seeds, at all events, grew out of the plant, and, as far as the language gives us any idea, in a similar manner, and by a similar law, and in a corresponding time, or succession of times, to that which regulated any subsequent seeding, or ripering, or fructification of the parent organism." And, again, "There was a previous nature in the earth, whether it had been in operation for twenty-four hours or twenty-four thousand years. We may compare this to a stream flowing on and having its regular current of law, or regulated succession of cause and effect. Into this stream we may say there was dropped a new power—supernatural, yet not contra-natural, or unnatural—varying the old flow, and raising it to a higher law and a higher energy, yet still in harmony with it. New causations, or new modifications of causation arise, and, after the successions and steps required, be they longer or shorter, a world of vegetation is the result of this chain of causation in the one period, and, through an analogous, if not similar process, an animal creation arose in another."—(The italics are mine.)—Professor Tayler Lewis' Six Days of Creation, p. 206, 216. 1855.—See, also, Darwin, p. 814, note.*

Such is the philosophy of the "typical" or "progressive developmental system," or spontaneity of living beings. It is defective, however, in assuming that the same "parturitive powers of the earth" which "gave birth" to the first plants and animals continue to operate now—and it is not true to the Sacred Record in affirming that—"no intimation is given that the first growth after the instantaneous starting power, or the utterance of the creative Word, was not as natural as any that followed," and then explaining away what is affirmed of the first appearance of the vegetable world, where it is most distinctly stated, and in remarkable consistency with the creation of man and animals in a state of maturity, that "the Lord God made the earth and the heavens, and every plant of the field before it was in the earth, and every herb of the field before it grew; for the Lord

^{*} See Notes Pr. page 1142, Qo, page 1145, and foot-note at p. 908.

God had not caused it to rain upon the earth, and there was not a man to till the ground;" thus, also, assigning the reasons. The author must, therefore, abide by his own authority. I may finally add that an examination of this subject occurs in my Essay on *Theoretical Geology*, to which reference is made at p. 908, § 1079, b.

Organic nature is one of the greatest embarrassments with which modern theoretical geology has been obliged to contend ever since Dr. Buckland discovered that the trilobite is endowed with eyes, and it has, accordingly, undergone many mutations as geologists have become somewhat informed of the laws of living beings. Nevertheless, such is the hidden nature of physiology, and not to be acquired by any extent of anatomical knowledge without a long and laborious study of the phenomena of living beings, and in their morbid as well as natural aspects, the propensity remains to group the organic world under the category of the inorganic. Examples of this nature are common enough, but, to carry out still farther one of the objects of the present section, I shall quote a paragraph from a work by the distinguished Alexander Von Humboldt, who, according to President Edward Everett, "owes his position in the intellectual world to his grasp of the whole domain of science and the majestic range of his generalizations." In his generalization of the forces and phenomena of nature, he undertakes, upon this scheme of philosophy as applicable to inorganic beings, to bring the organic world within the domain of that philosophy, a distinct enunciation of which occurs in his "Aspects of Nature."

"Reflection and continued study in the domains of physiology and chemistry," says this learned man, "have shaken my earlier belief in a peculiar so-called vital force. In 1797, at the close of my work entitled 'Versuche,' etc., I already declared that I by no means regarded the existence of such peculiar vital forces as demonstrated. Since that time I have no longer called peculiar forces what may possibly only be the operation of the concurrent action of the several longknown substances and their material forces." "I have said, in 'Cosmos,' 'The myths of imponderable matter and of vital forces peculiar to each organism have complicated and perplexed the view of nature." "Farther on in the same volume I have said, 'In a physical description of the Universe, it should still be noticed that the same substances which compose the organic forms of plants and animals are also found in the inorganic crust of the Globe; and that the same forces or powers which govern inorganic matter are seen to prevail in organic beings likewise, combining and decomposing the various substances, regulating the forms and properties of organic tissues, but acting in these cases under complicated conditions, yet unexpected [unexplained?], to which the very vague terms of vital phenomena, operation of vital forces, have been assigned, and which have been systematically grouped according to analogies more or less happily imagined."—p. 408-410.—Also, Institutes, p. 272, § 447 g.

Such is the opinion of an unusually vigorous mind, and remarkably enriched by an observation of nature; and if it can be of any advantage to the cause which he advocates, it is welcome to it. It is the high authority in science which this philosopher has so justly acquired, and the factitious importance which his opinion of organic life derives from its incorporation in "the majestic range of his general-

izations" that have led, in part, to its introduction here. But it should be considered that Von Humboldt was an unprofessional man, without any recognition as a physiologist in the department of organic nature, and that he was therefore rather less qualified to determine the merits of the question than many others who had made it the great topic of professional life, and least of all, was he entitled to employ his authority in speaking contemptuously of the doctrine which underlies the labours of Haller, John Hunter, Bichat, his own friend John Müller, and, I may add, of every man of note in medicine since the days of Hippocrates. It should, moreover, be considered that this degradation of man and other living beings formed an indispensable element in our Author's plan of the generalization of nature. Without it, Cosmos could not have been written. "The view of nature"

would have been otherwise too much "perplexed."

Besides the disposition which I have always endeavoured to manifest of affording the physical school of organic nature the opportunity of explaining their philosophy in their own unreserved way, I have also in view, in the present case, my oft-reiterated proof that it is the tendency of this generalization of the forces of nature to conduct its projectors and advocates to still greater violations of physiological laws, since those laws positively enjoin an ascription of the "first origin" of every existing species of animal and plant to a Supreme, Intelligent, Creative Power. But, since this is ignored by the doctrine which I am about to cite, there is necessarily an attendant implication that man and other organic beings were "brought forth," in the language of theoretical geology, "by the parturitive powers of the earth;" or, as explained physiologically, the properties impressed upon matter include a certain number of a vital, "slumbering," nature (§ 135 d, $250\frac{3}{4}$ a-f), through which the requisite 17 or 18 elements were assembled together, for every species of animal and plant, which then united them into an almost endless variety of precise ternary, quaternary, &c., compounds, then arranged them into a multitude of complex designs, developed reason and instinct, and ended by enabling man, and all mammiferous animals, and all unfledged birds, to provide sustenance for themselves in their state of infancy (\$ 32-57. 350\frac{3}{4} c-351, 1082, 1083. Also, INDEX I., Articles, Composition, Structure, Life, Vitalism and Solidism, Design, God and Nature, the original Essay on the Soul and Instinct, p. 158-172, being an Appendix on the foregoing subject, and the Essay on Theoretical Geology, § 1079 b).* Here is the intended paragraph from Cosmos, which lets us farther into the philosophy of "positive science:"

"Geographical investigations regarding the ancient seat, the so-called 'cradle of the human race,' are not devoid of a mythical character." Our Author then quotes approvingly from his brother William as follows: "We do not know, either from history or from authentic tradition, any period of time in which the human race has not been divided into social groups. Whether the gregarious condition was original, or of subsequent occurrence, we have no historic evidence to show. The separate mythical relations found to exist independently of one another in different parts of the earth appear to refute the first hypothesis, and concur in ascribing the generation of the whole human race to the union of one pair. The general prevalence of this myth has caused it to be regarded as a traditionary

^{*} I have shown that man, mammiferous animals, and birds, must have been created, ex necessitate rei, in a state of maturity both of mind and body.—See Note Pr p. 1142.

record transmitted from the primitive man to his descendants. this very circumstance seems rather to prove that it has no historical foundation, but has simply arisen from an identity in the mode of intellectual conception, which has everywhere led man to adopt the same conclusion regarding identical phenomena; in the same manner as many myths have doubtlessly arisen, not from any historical connection existing between them, but rather from an identity in human thought and imagination. Another evidence in favour of the purely mythical nature of this belief is afforded by the fact that the first origin of mankind—a phenomenon which is wholly beyond the sphere of experience—is explained in perfect conformity with existing views, being considered on the principle of the colonization of some desert island or remote mountainous valley at a period when mankind had already existed for thousands of years. It is in vain that we direct our thoughts to the solution of the great problem of the first origin, since man is too intimately associated with his own race and with the relations of time to conceive of the existence of an individual independently of a preceding generation and age. A solution of those difficult questions, which cannot be determined by inductive reasoning or by experience—whether the belief in this presumed traditional condition be actually based on historical evidence, or whether mankind inhabited the earth in gregarious associations from the origin of the race—cannot, therefore, be determined from any philological data, and yet its elucidation ought not to be sought from other sources." -Cosmos, vol. i., p. 355, Harper's edition.—My italics (p. 158, no. $5\frac{1}{2}$).

We may not be surprised, therefore, that our Author's generaliza-tion of nature embraces La Place's doctrine of the evolution of the solar system, and as inculcated in the "Vestiges of Creation" (p. 186, $\S 350\frac{3}{4} kk$), and now adopted, indeed, by many astronomers. The subject is invested with a certain degree of physiological interest on account of the constitution of the primary rocks, and the analogical reasoning which may be thence carried to the spontaneity of living beings from the assumed evolution of these rocks from a gaseous, chaotic state, exclusively through the properties impressed upon mat-This I have endeavoured to expound in my Essay on Theoretical Geology, and I recur to the subject now for the purpose of showing the harmony with which Cosmos has carried out the generalization of nature, and of giving to its system all the advantages that can inure from such consistency, or, on the other hand, of enabling it to accept, as graciously, the penalties of any defects, and thus subserve, in either case, some of the greatest truths and principles in nature and Religion. The following extract embraces the doctrine: when speaking of the origin of aerolites, he says,

"I would ask why the elementary substances that compose one group of cosmical bodies, or one planetary system, may not, in a great measure, be identical? Why should we not adopt this view, since we may conjecture that these planetary bodies, like all the larger or smaller agglomerated masses revolving round the sun, have been thrown off from the once far more expanded solar atmosphere, and been formed from vaporous rings describing their orbits round the

central body."—Cosmos, vol. i., p. 132.—Note Pp p. 1142.

It is not now my purpose to discuss the merits of the Mosaic History of Creation, as this is not the place, and, moreover, I have done

that in the Essay on Theoretical Geology. But it is appropriate to remark that if the want of "experience" disqualifies us for judging of the "first origin of mankind," as intimated in one of the foregoing quotations, and if we do not choose to accept the account of Revelation as "historical," it is highly incumbent upon physiological science to declare that the laws of nature utterly contradict the doctrine that organic beings were evolved by those laws, and that they therefore proclaim their dependence upon an Intelligent, Creative Power. the former case we have an ample amount of "experience," and if the latter be admitted, all nature ceases at once to be mysterious (§ 4½) b), and mystery associates itself with God alone. This doctrine of "experience," it must be allowed, has been carried to the same subject by distinguished physiologists (§ $350\frac{3}{4}l$), but it is as applicable to all the miracles and prophecies of the Old Testament, and to all the most essential means upon which the authenticity of Christianity depends, as to the origin of mankind; and it would be quite as fatal in science, and even in the ordinary pursuits of man, as it is to Religion. It is even possible that Humboldt would not have won laurels in America had it not been for the inductive philosophy of Columbus. Our Author appropriates in Cosmos the historical facts of the Old Testament so far as they relate to simply human affairs, because it alone informs us of that era of mankind, and this information was important to Cosmos; and herein lies the distinction between that experience which is so readily accepted on the mere testimony of man, and that in which man's agency is associated with Divine interposition, till it finally culminates in the distinction between experience and faith in their abstract relations.* A trust, therefore, in the merely historical facts of the Bible (for our Author has been defended upon this principle), is no proof whatever of a belief in Revelation, or in its Author—no more so than the Jew's trust in the biography of our Lord, as it respects His humanity, is a proof that he is a Christian. It is not unusual, indeed, for the mere Pantheist to employ the term creator as a sort of compromise with the Theist, and even to make professions of Christianity. But this has signally failed after the day of novelty, and personal influence, and mutual admiration has ceased, and the authors and actors have passed into history. Injustice is sometimes done, as was remarkably the case with the Religio-Medici, for, although it abounds throughout with evidences of the highest order of faith, yet its author incurred the charge of infidelity; and more than fifty years after his death, when time had extinguished animosities, Samuel Johnson thought it necessary to contribute the weight of his mind and character to the just cause of rescuing the Author's memory from this imputation, notwithstanding Browne had made an able defence of himself. But it shows the strong course of reason in its deliberations upon doctrines and professions.

Finally, besides the great question of the identity of the forces and laws of organic and inorganic beings, the remaining object of the present discussion has been equally in behalf of scientific interests, especially physiological; for nothing can be more opposed to the "experience" upon which are founded the facts and principles in physiology than the assumed or implied origin of living beings in the forces which rule the inorganic world; and coming to the intricate, but methodical constitution of the primary rocks, the evidence of a

^{*} He says in a letter to Varnhagen—"Possibly my Book of Nature is not sufficiently Christian for her Majesty," Victoria.—Letters, &c.

direct interposition of Creative Power in their formation is as palpable as in living beings, as manifested in the assembling of the numerous elements which compose the crystalline constituents, and in the methodical disposition of the three crystals in the bosom of each other which make up all the granite of the globe; or, if sometimes the three be united with a fourth, or that fourth replace one of the three in other granitic rocks, the same methodical arrangement obtains; all of which, with other characteristics, concur in yielding the same kind of testimony of supernatural dependence as the composition and structure of living objects, however probable it be in the former case that there was a subordinate instrumentality of the forces and laws impressed upon matter; while, also, the nebular hypothesis, and every other shape of the Plutonic doctrine, is absolutely contradicted by the water which enters into the composition of the primary rocks, by the uniform absence of all traces of fusion among the crystals, and especially, also, by the vast differences in temperature at which those crystals, and that water, and the numerous metallic substances, undergo condensation, besides an array of other facts whose introduction here would be inappropriate, but which I have considered extensively in the Essay on Theoretical Geology. Here, therefore, is something for the senses, something from "experience," something demonstrable through the established facts and laws in chemistry and physfcs. Still, however, it is certainly to be expected that all who neglect the facts which declare the "first origin" of man and other living beings in an Intelligent, Creative Power, and refer their origin to the powers of nature, will unhesitatingly ignore the corresponding facts in their relation to the earth, and assemble the whole under a common generalization. A critical attention, also, to the writings of those who sustain the nebular hypothesis will result in the conviction that they are equally pledged to the doctrine of the evolution of organic nature through the powers alone which appertain to matter.

Science, for its own sake, especially physiological science, should be consistent with itself. Nor may we exclude from the interests of the latter the cosmogony of the nebular hypothesis, for, as I have shown, such is the elementary composition of the primary rocks (seven elements for feldspar, ten for mica, and which, according to the nebular hypothesis, must have existed, along with all other terrestrial things, in a perfectly blended condition), and such the uniformity and arrangement of the crystalline substances, and such, therefore, the ground for analogical reasoning, that were it conceded that the main bulk of the earth was brought into its organized condition by its own properties alone, it would be a vain attempt to refute the doctrine of the spontaneity of living beings by any demonstrations founded on their elementary composition and constituent parts. To assume, as does the nebular hypothesis, and that of the spontaneity of living beings, that the elements of matter were endowed with the independent power of generating their organized conditions, is so contrary to all experience (for the artificial production of crystals, or as witnessed in natural progress, bears no proper analogy to the complexity of the primary rocks), that it supposes a condition of things which is equivalent to Creative Energy. It is an illusion, therefore, to imagine that science divests itself of causes that elude its ambitious grasp by assuming that "blind material forces" will explain the origin

of both living beings and the primary crystalline rocks, since, in either case, it demands a condition of forces and laws which experience assures us, and science admits, does not exist at present; or, if it be content with a simple expression of ignorance of the organizing causes, from "want of experience," it is equally an admission that terrestrial beings originated in causes which have no existence now, and therefore not belonging to the constitution of nature. The plea of a "want of experience" simply means that the causes which gave origin to organic nature and the primary rocks ceased their operation before the observations of men began. They have therefore no longer an existence; otherwise, they would continue to operate, and new animals and plants, if not granitic rocks, &c., would be presenting themselves. Science, therefore, in separating from Supernatural Power convicts itself of inconsistency; and the essential difference between the supposed "parturitive power," and the co-operation of Divine Power with the properties impressed upon matter, in expounding the problem before us, whether it respect the organization of the earth or of living beings, consists in the neglect, in the former case, of all the evidences of Design, and in a disposition to lean upon the atheism of pantheism. But this in no respect compasses the abstract object of the disciples of nature, for there still remains the crushing fact that it is contrary to all "experience," to all that is known of nature, to suppose that living beings, or the primitive earth, emerged from the elements of matter without at the same time supposing that some supernatural agency was concerned in the works. In the one case, therefore, science stultifies itself, while, in yielding to the agency of an Intelligent Creative Power, it simply obeys the exigencies of the facts and the dictates of that reason which professes to be a rude imitator of some of the Designs which challenge its faith in a higher order of Reason (§ 350\frac{3}{4} f-i, \bar{l}, 1079 b, 1083).*

The Glycogenic Function of the Liver.

§ 1086. Among the subjects discussed in the Appendix to this work is the important one of the supposed glycogenic function of the liver. Had this anomalous complication of functions, with all its other attendant peculiarities, been attributed to the liver only, it would have been more difficult to have arrived at the real facts in the case. But the discoverer has recently not a little invalidated the plausible experiments which had conducted him to his conclusions by assigning this same function to the placenta "during the early period of fætal life." This appears to have been a kind of corollary from the imputed function of the fully-developed liver and its immaturity during the early period of feetal life, but resting upon experimental observation. That such a coincidence should exist between two organs so differently constituted, and whose principal offices are so dissimilar in the economy of life, may well raise our admiration; and this the more so, as the glycogenic function of the placenta is said to disappear, along with its special anatomical provision, as soon as the fætal liver has advanced to a maturer development. Nature, therefore, to be consistent in this remarkable scheme, should have allotted, also, to "the transitory glandular or epithelial element of the placenta," as to the mature liver, the vicarious function of secreting bile; and hence, should the glycogenic function be established, and * See Notes Pp p. 1142, Qq p. 1145.

the exact disappearance of the glandular element when it is no longer necessary to the exigencies of feetal life, we may expect to hear from the eminent physiologist that he has demonstrated the co-existence of the two hepatic functions in the placenta. But the original supposition relative to the liver was apparently encumbered with difficulties, as was shown in sections 1031-1033, and the "vicarious" nature of the supposed temporary office of the placenta would seem to belong to the category of the "vicarious spermatozoa," as represented in section 83 b, or to what is perhaps more analogous in b 493 c.

The Cause of the Blood's Fluidity.

§ 1087. It was a very ingenious, and so far as appearances went, a plausible demonstration of Dr. Richardson's, in his prize essay, that the blood owes its fluidity to the presence of ammonia. This is a question, however, not to be determined by chemical experiments, or by any other outside of the living body. If experiments with pepsin, or the "digestive mixture," could not stand the test of organic philosophy, nor even of experimental philosophy (p. 781, § 1029), it was scarcely probable that those would long endure by which the new doctrine of the blood's fluidity was very plausibly commended to the attention of the physiological world; and the only apparent objection about it was, that it did not insist that the heart and blood-vessels are stimulated into action by the solvent principle of the blood. It may have been foreseen that such a theory would imply great fluctuations beyond the standard frequency of the pulse, according to the variable proportions of ammonia. But it is at least certain that, whenever such experiments have been attempted upon this organic, living, complex fluid, whatever their nature, they have been shown to be fallacious, and such has been the early fate of this new hypothesis in the hands of Brück and Zimmermann, the former particularly sustaining the Hunterian theory that the fluidity is owing to a vivifying influence exerted upon the blood by the sanguiferous organs, while the latter very justly supposes that the coagulation of abstracted blood is due to chemical transforma-These transformations are prevented, while the blood is circulating, by the influences of the blood-vessels which maintain its vitality. When those influences are withdrawn, the oxygen and other elements of the fluid pass very quickly under the operation of chemical affinities, as set forth in section 54 a. I may finally add that, when the various characteristics of the blood, such of them as are represented in many parts of this work, as in sections 688 ee, 846, 847, 952, 953, are duly considered, it must be admitted that such phenomena evince the dependence of the blood's fluidity upon a cause appertaining to the constitution of the blood itself, while other obvious considerations place it beyond doubt that so important a condition of the pabulum vitæ is not committed to the physical action of any one of its constantly-fluctuating constituents; for if ammonia be truly one of them, it must be as liable to variations, at least in proportions, as the serum, globules, etc., and the fluidity of the blood, therefore, exposed to the same instability. Richardson's clever observations have been accepted by other physiologists; but they are a part of the "experimental philosophy" of the day, whose factitious analogies have been so extensively and powerfully arrayed

against the great laws of organic beings, and the subject is introduced here as tributary to the objects of these Institutes.—See HUMORAL PATHOLOGY, Index II.

THE MODUS OPERANDI OF REMEDIES.

§ 1088 a. As principles and sound analogy, the great ends of science and the basis of the healing art, are of very secondary moment with the speculative as well as the practical masses of mankind, a demand is apt to be made for specific demonstrations of every problem that may arise in the vast range of observation. It is not enough, for example, that it be shown of a thousand things that they exert their morbific or remedial effects through natural physiological laws, and that when their influences extend to parts remote from the seat of their application it is through the medium of the nervous system. Each particular fact must be settled experimentally as if it had no law governing its condition. This propensity must be gratified, and it will doubtless end, also, in satisfying all that organic nature is perfectly consistent, throughout its mutations, in all its laws and principles.

The foregoing considerations lead me into a farther proof that certain substances, particularly arsenic and strychnine, which are supposed to exert their effects by absorption, have been again shown to be incapable of detection within the organism when administered in poisonous doses. Two cases of this nature, where large quantities of strychnine (two scruples in one of them), and six experiments upon animals by poisoning with the same substance, are related by Dr. Alfred S. Taylor in Guy's Hospital Reports (1856, vol. ii), in which none of the poison could be detected in the blood or tissues. Another case is related in the same Reports (1857, vol. iii), in which Prof. Christison, and Dr. Maclagan of Edinburgh, and Prof. Geoghegan of Dublin, to whom parts of the body were sent, and Dr. Taylor, failed of detecting the poison. Here occurs, also, the case of Rev. Dr. Alexander, who died from poisoning by arsenic, but in whom none of the metal could be found.

Absorption by the Skin.

§ 1088 b. Experiments, also, showing that the skin in its natural condition absorbs nothing, even in a state of solution, continue to be multiplied; and yet we are constantly told in the books that remedies applied to this organ produce their effects by absorption into the circulation. Let us have, therefore, some of the late, reiterated experiments in reference to this question. Thus, it is stated in the report on Physiology in the London Medico-Chirurgical Review for Jan., 1857, that,

"The inferences regarding the absorption of saline or organic substances dissolved in water (in Duriau's experiments with the warm bath) are based on the examination of the urine before and after the use of the bath. Iodine and ferrocyanide of potassium, carbonate of potash, sulphate of quinia, and other salts, were employed. The reaction of the urine after the bath was always alkaline, even when nitric acid had been added to the bath. Potash and soda were the only bases found in the urine—no trace of iodine, cyanogen, &c.

"Poulet draws the following inferences from his experiments: 1.

That the urine becomes alkaline after acid, as well as after alkaline baths. 2. After friction of the skin with a solution of tartrate of antimony or extract of belladonna, &c., none of these substances were found in the urine. 3. The skin absorbs, therefore, neither water (?) nor substances dissolved in it, as long as the epidermis is entire.

"Kletzinsky's experiments likewise confirm the non-absorption of salts through the healthy epidermis."—See *Index II.*, Articles Humoral Pathology, Skin, Cold, Counter-Irritants, Seton, Plas-

TERS, REMEDIES. Also, Experiments, § 481-484, 494 b-e,

§ 1088 c. It is worthy of remark, however, that experiments of the foregoing negative character have little influence upon doctrines of so much simplicity, and of such comprehensive and ready application in pathology and therapeutics as humoralism and the operation of remedies by absorption. It therefore continues, as ever, to be a prevailing belief that, among other things, the numerous preparations of mercury are absorbed both by the skin and the intestinal canal, and, entering the circulation, not only thus accomplish their effects, but become deposited in the tissues (§ 851). Thus lodged in the system, they are supposed to inflict the manifold evils that are due to vicious habits, or other foreign causes. But the most curious circumstance attending this hypothesis, and which must not be omitted in this record of "experimental philosophy," a practice has obtained extensively of immersing these subjects in iodine baths, for the purpose of dislodging the supposed offender. But the facts being against the philosophy, at least as it respects the skin, and as iodine baths have been said to effect the liberation of mercury from the system at long intervals after the administration of the latter remedy, we may safely conclude that what has been asserted by Professor Lorinser, and others, of a similar effect by the internal use of iodine, is equally a mistake, especially when connected with the various facts which I have alleged against the supposed absorption of mercury.

Nevertheless, it may be said that negative facts cannot contradict the affirmative. But, in the first place, are the affirmative reliable (§ 51-6)? Are not the senses apt to be deceived by preconceived hypotheses? Why, if many remedies of a very irritating nature operate by absorption, do they not manifest their action upon the heart as readily as upon organs that are incomparably less irritable (§ 829)? Is not this consideration alone an insuperable objection to the hypothesis of absorption? If it be answered that reflex actions of the nervous system excited by remedial agents should, in conformity with the principles which I have advanced, be equally liable to affect the heart, it would only evince an ignorance of the most obvious laws of the nervous system, and which, in this aspect of their remarkable characteristics, I have endeavoured to illustrate in former sections (§ 2333; 500j, k, m, &c.). The wonderful endowment of the nervous system by which it receives and reflects impressions upon particular parts and avoids all other parts, according to the nature of the exciting cause and other special circumstances, readily explains, and can alone explain, the phenomenon in question, especially considering its remarkable frequency. And here I may add to what I have said of the operation of anæsthetics through reflex action of the nervous system, that the law of elective influence (§ 233\frac{3}{4}, 500 j, k, &c.) explains completely the limitation of their effects to the organs of animal life, while

the doctrine of absorption is contradicted by that limitation (§ 827 b, 1066), as is the doctrine in its broadest sense by local diseases.

Finally, the foregoing negative observations (§ 1088 α , b) are as good, at least, as the affirmative; and since, therefore, it is thus shown that many remedies that have been supposed to always operate by absorption do sometimes produce their effects upon various parts without being taken into the circulation, and therefore by no other conceivable method than that which I have indicated, the consistency of the laws of nature is such as to assure us that the same remedies always exert their effects upon parts remote from their seat of application through alterative influences of reflex action of the nervous system, and that, if they be sometimes absorbed, the present and foregoing considerations, as well as a multitude of others which occur in this work, equally assure us that they are admitted in such small quantities as to produce no effect whatever, not even upon the very irritable heart. (See *Index II.*, Articles Remedies, Reflex Action, Nervous Power, &c.)

Transfusion of Remedies into the Circulation.

§ 1088. d. The foregoing sections upon absorption will remind some of our readers of an experiment performed a few years ago by Prof. Buckheim, of injecting a solution of about half an ounce of sulphate of soda in two ounces of water into the jugular vein of two dogs without any effect upon the intestine, while both animals were purged freely by the same dose when administered by the mouth. The demonstration is, of course, conclusive against the prevailing doctrine of operation of cathartics by absorption, and proves that they exert their direct effects upon the mucous coat of the intestine, and by reflex action of the nervous system upon the muscular coat, and upon all other parts that may feel their influence. In the present case there is not only the assurance arising from the failure of the injected substance to excite the slightest action in the intestinal canal, but the interpretation supplied by the exciting effect of the nervous influence when reflected upon the intestinal muscular tissue through the direct irritation of the mucous when the cathartic was swallowed; since, no action being manifested in the case of the injection, all the results from swallowing the agent must, of necessity, be referred to the same causation that increased the peristaltic movements (§ 889 a). But these are facts which lie in the depths of philosophical medicine. To be duly appreciated there must have been a laborious study of the profound laws in physiology, especially such as are relative to the nervous system in its connection with organic functions. In any event, the experiments cannot fail of establishing the conviction that remedies do not operate by absorption, and sustain my conclusions as to the fallacious nature of this kind of "experimental philosophy" (§ 830-837). Also, Index II., Articles, CATHARTICS; OIL, CASTOR; Humoral Pathology.)

Absorption through the Epithelial Cells of the Intestinal Tube, and Lacteal Circulation.

§ 1089. The following observations, so far as they go, corroborate the doctrines in this work (§ 275-294, &c.), and in the Medical and Physiological Commentaries, upon the subject of endosmose and ex-

osmose, and more particularly the manner in which substances are

taken up by the absorbents.

"Von Wittich," says the London Medico-Chirurgical Review for July, 1857, "contributes an observation of great importance regarding the question at issue (the passage of solid molecules through the epithelial cells of the intestinal tube). A rabbit killed (by bleeding) six hours after it had been bitten in the back by a dog, and thus deprived of the use of his posterior limbs, exhibited the chyliferous vessels originating from the lower half of the ileum filled with an entirely red fluid. This redness was shown to be caused merely by the admixture of the red blood-globules in a large proportion, not by that of coloring matter. The corresponding part of the intestinal tube contained mucus mixed with blood, after the removal of which the mucous membrane manifested the appearance of fine red dots, which, by means of a lens, were recognized as villi filled with blood. Wittich does not hesitate to explain this state of things by adopting the view, that the blood-globules pass as such through the epithelial cells and the parenchyma of the villi into the chyliferous vessels; but is of a similar opinion regarding the entrance of fat and other minutely divided solid substances into the absorbent vessels." found the same true, also, of the chyliferous vessels of the cæcum.

The foregoing observations had been recently made by others, one of whom I shall quote upon the particular question, for the sake of other facts, as related in the *Med. Chir. Rev.* for January, 1854.

"Brücke states, as the result of his observations and experiments (on man, swine, and other mammalia), that the cylindrical epithelial cells of the mucous membrane of the intestines, through which the chyle passes on its way to the lacteal vessels, do not, as is generally supposed, consist of a closed cavity surrounded by a complete membrane, but that this cavity is isolated from the intestinal tube merely by a thin layer of a mucilaginous substance. Brücke asserts also that they possess a small opening on their opposite side, through which the molecules of fat pass into the interior of the villi" (§ 295). And he goes so far as to say that one of "the mechanical means for the movement of the chyle is the muscular contractions of the intestinal tube by which the chyle is pressed into the villi." Why not, then, other things "pressed in;" and is not the analogy supplied by plants of some application here? ($\S 289-291$, p. 166, $\S 350$, nos. $26\frac{1}{2}$, 27, the parallel columns, 826 a.) It is an important and sound conclusion, however, and in which Von Wittich and Moleschott agree with Brücke, in opposition to the prevailing doctrine (§ 1054-1055), that, "When the villi are filled, their muscular fibres contract, and the fluid they contain is pressed into the channels lying between the mucous and submucous membranes," and that, "from the lacteals within the walls of the intestines the chyle is propelled by means of the muscular contractions of the tubes into the vessels of the mesentery, from whence it is pumped up by means of the respiratory actions into the thoracic duct;" or rather, as I have endeavoured to show, "pumped up" by the derivative or suction power of the right cavities of the heart. (Indexes, Circulation of the Blood, Lacteals, VEINS.)

In all the discussions upon the foregoing subject we hear nothing of the intestinal veins being concerned in the function of absorption,

although this is as much a matter of general belief as in Magendie's

day (269, 829).

Doubtless, the essential fact relative to the intestinal villi was well ascertained by Mr. Cruikshank, in the presence of Mr. Hunter, whose statement I quoted in the Med. and Physiolog. Comm. (1840), that they had seen the villi distended with chyle, and had no difficulty in seeing the open orifices. I shall also repeat here, for pathological as well as physiological purposes, a quotation which I made, in the article upon Endosmose and Exosmose (vol. i.), from R. Jackson on Febrile Diseases. Thus: "R. Jackson, in speaking of the enlarged blood-vessels of the villous coat of the intestines (in yellow fever), remarks that 'in some instances the mouths of the canals were visible at different points in the interior surface, yielding a dark-coloured fluid by pressure.' Again: 'The mouths of ducts-not blood-vessels —were discovered on the interior of the colon, containing a dark-coloured fluid.' 'Proceeding farther with the investigation, similar canals discharging a tar-like fluid into the interior of the stomach, more especially near the upper orifice, were in like manner discovered in almost all cases where black vomiting had been a conspicuous symptom of the disease. The appearances were noted, and they were often verified by inspection.' As to the open termination of the villi, we are not insensible of our solitary position, since it is stated in the British and Foreign Med. Review that 'almost every modern physiologist has now abandoned the idea that the absorbents commence by open mouths on the villous coat of the intestines.' This opinion we are certainly bound to respect so far as it is supported by any facts, or is not contradicted by others."—Medical and Physiological Commentaries, ut supra.—Also, Institutes § 275.

The Forces which Circulate the Blood.

§ 1090. The following quotation is made from the British and Foreign Med. Chirurg. Review of January, 1859, simply for the reason that it sustains several of the principal conclusions set forth in this work, and originally in the Medical and Physiological Commentaries upon the important subject of the forces by which the blood is circulated. See Index II., article Circulation of the Blood.

"Nelson considers the diastole of the heart as the effect of an active movement. He assumes that the heart muscles, unlike voluntary muscles, are possessed of a double power—that of expansion as well as of contraction. The distention of the ventricles, the Author says, 'is an active and inherent force.' The mechanical forces acting on the movement of the blood in the veins are: 1. That furnished by the heart and arteries; 2. That by the pleural vacuum of the thorax; and, 3. The expansive power of the auricle." These, however, are only a part of the forces concerned, nor do I suppose that the expansion of the thorax is much of an element, as I endeavoured to show in the Medical and Physiological Commentaries.

As to Oesterreicher's old experiment of placing a heavy weight upon the heart of a frog and deducing from it the important conclusion that the dilatation of the organ is not an active movement, and which continues to be quoted as an unquestioned authority, I show in the Commentaries that the experiment proves exactly the contrary.—Med. and Physiolog. Comm., vol. ii., p. 399-402. Also, Note Bb p. 1131.

New York, 1859.

INDEX I.

ABSORBENTS,

consist of the lacteals and lymphatics; one for formative, the other for destructive purposes, p. 129, § 273. See, also, VEINS, TISSUES, and AB-SORPTION.

ABSORPTION,

description of the function, &c., p.

128-134, § 268-295.

comparative view of its physical philosophy with that of digestion, animal heat, bloodletting, humoralism, inflammation, &c., p. 99, § 192; p. 132, 133, § 289-292; p. 197, § 362; p. 238, § 438 b-d; § 556, § 699 c; p. 482, § 744; p. 484, § 748; § 837, § 823; § 841, § 863 e; § 873, § 906 a; § 904bb, § 909, 910, 1088-1089.

of unnatural agents, depends upon morbid changes in initiability p. 00

morbid changes in irritability, p. 99, 192; p. 129-134, § 277-295; p. 519-521, § 826-827; p. 677, § 904 c.

operates universally through the lymphatics, and without the aid of any specific stimulus, p. 46, § 74 a, but requires a specific stimulus in the lacteals. See NUTRITION.

Aconite, Atropia, Strychnia, Hydro-cyanic Acid, Carbonic Acid Gas, NITROUS OXIDE GAS, SULPHURIC

Етнек, Товассо, &с.

their effects upon organic life, and mode of operation, p. 66, 67, § 143, 148-151; p. 318-321, § 493 d-494; p. 415-418, § 648 c-652 c; p. 420, \$ 654 a; p. 522-525, \$ 827 b-828 c; p. 672-674, § 904 b.

ADAPTATION, LAW OF,

propounded by the author in a series of propositions, p. 45, § 73 a; p. 46, δ 74 a; p. 58, 59, δ 129; p. 61–63, δ 136–137; p. 65, 66, δ 143; p. 67, 68, § 149-152; p. 69, § 156 b, and references there; p. 89, § 188 a; p. 90, \lozenge 188½ a–c; p. 93–95, \lozenge 188½ d; p. 98, \lozenge 191 a, b; p. 99, \lozenge 192; p. 101, 102, \lozenge 201–203; p. 107, \lozenge 226; p. 110, 111, \lozenge 233–233¾; p. 330, 331, \lozenge 500 m, o; p. 350–361, \lozenge 524–529; p. 430-433, § 675; p. 531, § 837 cc-839; p. 535-539, § 847-849; p. 542, § 843 c, d; p. 545, § 859 b; p. 553, § 870 aa; p. 555, § 872 a; p. 561, 562, § 888 a-d; p. 565, 566, § 889 g-k; p. **570**, $0.889 \, \hat{n}$; p. 580, 581, $0.890 \, \hat{n}$; p. 580, $0.890 \, \hat{n}$; 582-585, § 890½-591 e; p. 586-588,

Adaptation, Law of-continued.

§ 891 g-l; p. 592, 593, § 891⅓ k; p 597, § 892 c; p. 601, § 892 g; p. 605, § 892 m-p; p. 607, § 892 r; p. § 893 c-i; p. 658-660, § 893 p-r; p. 662–664, § 895–899; p. 669, § 902 h, i; p. 670, § 902 m; p. 679–683, § 905; p. 684-688, § 905½ b, c; p. 692-694, § 914-923 b; p. 698-709, ◊ 929-951.

Adhesion. See Inflammation.

ADULT AGE,

its physiological and moral character

istics, p. 380-381, § 579. Affinity, Vital. See Vital Affinity.

its physiological and moral characteristics, p. 373-383, § 574-584.

ALIMENTARY CANAL,

experiments to determine the Principle upon which its Action depends, p. 315 ALLOTROPISM,

applied to illustrate the philosophy of

life, p. 99, \Diamond 191 d. Alston, Dr. (1733)—shows that opium is not absorbed, but acts through nervous system, p. 308, § 484, a, b.

ALVINE DISCHARGES,

in their relation to disease, p. 452-455, § 694, 694½

Alkaloids of Cinchona,

their therapeutical uses, p. 593-607. ALTERATIVES,

all things such, moral and physical, which are capable of changing the existing condition of the vital states, p. 542, § 854 c; p. 662-665, § 895-901.

in large doses or degrees their remedial or morbific effects may be speedy and profound; in small and frequently-repeated doses or degrees, the same effects may be only gradually established, in conformity with the fundamental plan of organic nature, p. 89, 90, § 188-188½ b; p. 107-110, § 226–232; p. 122, § 240; p. 210, § 387; p. 214–217, § 393–399; p. 222– 227, § 409 c-411; p. 230-232, § 421-424; p. 250, 251, § 441 c; p. 260-265, § 445–447 b; p. 272, 273, § 447 h; p. 280, § 449 d; p. 283-287, § 452-458; p. 290, § 462, 463; p. 295, § 476 a; p. 323-332, § 498 f-500; p

Alteratives—continued.

excited by dividing nerves, p. 289, § 461.

its sympathetic or constitutional effects; see above, and Fever. I add, that the dependence of the "fever"

Inflammation -- continued.

upon the local disease, and other distinctions between true fever and inflammation, are well shown by the apparently opposite constitutional effects of poisonous doses of arsenic; as they may happen to produce in-flammation in the gastro-mucous membrane of one subject and not of another. The difference proves, also, that the poison does not operate at large by absorption, but according to its special effects upon the stomach. See the principle, p. 665-670, § 902; p. 679-681, § 905. Also, Humoralism.—Note L p. 1120.

distinguished from Fever. I add to the distinctions which I have set forth in sections 141 b, 148, 675, 712-722, 757, 759, 764 a, 764 e, 770, &c., that when inflammation is attended by a chill, this phenomenon generally happens only when the disease is on the decline; that is to say, when suppuration is taking place. In fever, on the contrary, it denotes the stage of the most intense morbid action.

chemical theory of, and of Fever, p. 160, § 350, No. 10; p. 175, § 350½ h-l; p. 176, 177, § 350¾ a, 350¾ e. INDEGANIC KINGDOM. See KINGDOMS OF

SCHOOLS OF MEDICINE,

three: Physiological or Vital, Chemical, and Chemico-physiological, p

6, 7, $\sqrt[6]{4\frac{1}{2}} a - e$.

the Physiological contradistinguish organic and inorganic Nature, p. 6, ϕ $4\frac{1}{2}a$; the Chemical confound organic and inorganic Nature, p. 6, § 4½ b; the Chemico-physiological compromise philosophy, p. 7, $64\frac{1}{3}c$; p. 197. § 361.

SECRETION,

the function upon which nutrition and growth immediately depend; better designated as Appropriation, p. 217 -227, § 400-411.

Secretion—continued.

chemical philosophy of, p. 168-170, § 350, Nos. 31, 32, 37, 38, 39; p. 180-182, § 350\frac{3}{4}e,f. See,also,Combustion.

Secretions and Excretions,

terms applied to the products of the functions, and used, at present, in their morbid acceptation, and as supplying symptoms, p. 450-455, § 690-694

SEDATIVES,

their uses and mode of action, p. 583-593, ◊ 891–891½; p. 681–683, ◊ 905 b. See, also, NARCOTICS, HYDROCLANIC Acid, and Analogies.

SEED,

its state of life, p. 30, § 57; p. 97, § 190 b.

evinces great Design, p. 56, § 123; p. 97, § 190 b. See, also, Ovum.

SEMEN,

a vital stimulus, p. 44-46, § 72-73; p. 47-49, § 75-80; p. 97, § 190 b. acts upon the ovum, p. 44, § 72; p.

97, § 190 b.

transmits disease, p. 47-49, §.75-80. its analogies with other vital agents, p. 45, § 73, 74; p. 97, § 190 b.

imparts constitutional peculiarities, p. 44, § 72.

vicarious, p. 50, §83 b. See, also, Ovum.

its merits in croup, p. 638, $6892\frac{4}{5}f$. SENNA,

objections to its common use; see CATHARTICS, and THERAPEUTICS.

SENSATION,

its philosophy, p. 89, § 186, 188 b; p. 100-103, § 194-204; p. 280-283, § 450-451.

of three kinds, common, specific, and sympathetic, p. 280-283, § 450-451.

common, the cause of pain, and universal, p. 100, § 198; p. 281, § 450 d. specific, the function of the senses, and the fountain of knowledge, p. 100,

§ 199; p. 281, § 450 e.

sympathetic, concurs with the nervous power in producing the function of remote sympathy, p. 101-103, § 201 –204; p. 107, 108, § 227; p. 282– 284, § 451–453; p. 290, 291, § 462– 467; p. 323-332, § 500.

sympathetic develops the nervous power, p. 101, § 201; p. 107, § 227.

common and specific terminate in the brain, and end in exciting perception, p. 100, § 196, 199½; p. 101, § 201; p. 280–282, § 450 c-451 b.

common and specific require the exercise of perception, p. 124, § 241 d;

p. 281, § 450 e.

sympathetic may terminate in any part of the nervous system, does not affect perception, but ends in exciting

Sensation—continued.

the nervous power, p. 101-103, § 201 242; p. 107, 108, § 227; p. 124, § 242; p. 281–287, § 451–459 a; p. 321, § 497; p. 323–332, § 500; p. 342, 343, § 515, 516 d, Nos. 3, 4; p. 349, § 520-522; p. 353, § 524 d, Nos. 4, 5, 6.

common and specific may result in the development of the nervous power by exciting the mental emotions along with perception, when the emotion develops the nervous power, or sympathetic may be in simultaneous operation through nerves of organic life, p. 101, § 201 a; p. 103, § 209; p. 341, § 514 m. See, also, PAIN, and MENTAL EMOTIONS.

sympathetic is appropriated exclusively to organic life in animals, since the nervous power operates upon irritability in developing motion, and mobility in its functions in animal life is only a modification of the same property in organic life, p. 89, § 188 a; p. 103, § 208; p. 110, § 233; p. 126, 127, § 258–260; p. 323–332, 500; p. 349, § 519; p. 671, § 903. See, also, Nervous Power.

common and specific depend mostly upon cerebro-spinal nerves, p. 101,

102, § 201.

sympathetic depends mostly upon the sensitive fibres of the ganglionic and pneumogastric nerves, p. 102, § 201 c

sympathetic is necessary to reflected motion, but never operates when motion is generated by causes acting directly upon the nervous centres, p. 101, § 201; p. 107, 108, § 227; p. 671, § 903, and ut cit. what is its chemical rationale in con-

nection with Perception and Sympathy, p. 85, § 175 c; p. 155, § 349 e; p. 281, § 450; p. 329, 330, § 500 n

SENSIBILITY,

peculiar to animals, p. 100, § 194. "organic" is irritability, p. 99, § 193; p. 101, § 201 a; p. 671, § 903.

the great inlet of knowledge, p. 100, \$ 195; p. 281, § 450 e.

receives and transmits impressions, p. 46, § 74 a; p. 89, § 188 b; p. 93–96, § 188½ d-189 c; p. 100, § 195; p. 101-103, § 201-204; p. 281-283, § 450 e-451; p. 671, § 903.

its organs, the nerves, p. 100, § 196;

p. 280, § 450 b.

is of three kinds, p. 100, § 196; p. 280, § 450 a.

common, belongs to all parts; the source of pain; generally dormant in organic life, but roused by disease, p. 100, § 198.

Sensibility-continued.

specific, peculiar to the senses; exquisitely susceptible, but rendered obtuse by disease, p. 100, § 199; p. 281, § 450 e.

common and specific, relative to the brain, or its equivalent, alone as their center; the sources of true sensation; require the exercise of perception, p. 89, § 188 b; p. 100, §

199½; p. 280, § 450.

sympathetic, an element of remote sympathy, p. 46, § 74 a; p. 89, § 188 a; p. 101-103, § 201-204; p. 104, \lozenge 209; p. 282–284, \lozenge 451 c–453; p. 671, \lozenge 903; is relative to the brain, spinal cord, and ganglionic system, as its centers, p. 101, 102, § 201; p. 287, § 459. See, also, Sensation, sympathetic may terminate, &c.; effects of, reflected from nervous centers, p. 89, § 188 a; p. 101, \$ 201; p. 108, \$ 227; p. 223-232, § 500; necessary to reflected motion, ibid; resides especially in the sympathetic and pneumogastric nerves, p. 102, § 201 c; p. 104, § 209; does not involve true sensation or perception, p. 101, § 201 b; p. 103, § 204.

possesses modifications analogous to those of irritability, p. 100, \lozenge 200; p. 102, \lozenge 203; p. 108, \lozenge 227.

common, low in the nervous centers, p.

107, § 224.

less in trunks than nervous ramifications, p. 107, § 224; p 347, § 516 d, No. 11; p. 521, § 826 d.

its general relations to external objects, p. 53, § 100; p. 398-400, § 626-630.

STETHOSCOPE,

its advantages, p. 640, § 8924 h.

STIMULANTS,

their uses, &c., p. 579-583

STIMULI, VITAL, p. 21, § 21; p. 62, § 136, 137; p. 90, § 188½. every part has its own, p. 62, § 136. Stimuli, Vital-continued.

of one part offensive to other parts, p. 63, § 137.

certain natural ones acted upon and appropriated to various uses, p. 90, § 188½ c; p. 107-111, § 226-233¾.

their adaptation to parts, p. 62, § 136; p. 63, § 137 c. See, also, VITAL AGENTS, and ANALOGIES.

STOMACH,

alone generates a digestive fluid, p. 62, § 135 a; p. 191, 192, § 353; p. 229, § 419.

induction from, of the vital nature of decarbonization of the blood, p. 229, 230, § 419, 420. See, also, Carbon, and Mucous Tissue.

its peculiar product artificially prepared, p. 197-202, § 362-3761.

its variety of structure and comprehensive relations in the function of assimilation, p. 140-147, § 305-330.

formative not destructive, p. 15, § 13, 14; p. 16, § 16–18; p. 24, § 42; p. 30, § 59; p. 33, § 60; p. 135, § 301; p. 143, § 322; p. 196, § 360, 361; p. 200, § 374, 375.

chemical theory of its function of digestion, p. 167-170, § 350, Nos. 29-34;

p. 197-199, § 362-364½.

its usual unaltered state after death, adverse to the chemical theory of digestion, ut supra.

his opinion of the times, p. 203-207, § 3763 a.

STRAMONIUM. See Aconite, &c.

STRENGTH AND WEAKNESS, OR DEBILITY, in what they consist, p. 370-372, § 569; p. 312, 313, § 487 g, h.

STRUCTURE,

its physical and vital characteristics, p. 50-73, \$83-163.

important to be known in its sensible and functional character, p. 51, § 83 c. its minuteness, unimportant to know,

p. 59, 60, § 131. composed of Tissues, p. 52, § 85–88.

See, also, Tissues.

its vital characteristics, p. 52-73. See, also, Tissues.

in plants and animals, how different, p. 54, 55, \$ 107-117; p. 134-140, \$ 293-304. See, also, Plants.

of organic beings, heterogeneous, p. 20, § 29.

its ultimate intricacy, p. 59, § 130. created before life, p. 81, § 170.

STRYCHNIA,

effects on the nervous system, see Ac-ONITE, &C.

Suporifics,

the term objectionable, p. 250, 251, \$ 441 c; p. 335-341, § 512-514; p. 547, § 863 d; p. 550, § 863 e; p. 630,

| Sudorifics—continued.

§ 8923 b; p. 661-664, § 894-900; p. 666-669, § 902 b, i; p. 678, § 904 d, &c.; p. 704, \$ 943 a, b, 944 a.

many agents, like hot water, &c., may induce far greater diaphoresis than the antimonials and ipecacuanha; the former excite the circulation, the latter, like loss of blood, depress it, and perspiration is in proportion; the former of no useful effect or injurious, the latter profoundly curative, ibid. See, also, REMEDIAL AC-

TION, and ALTERATIVES.

the author's philosophy of nervous influence places the phenomena of petechial effusions of blood under the skin during the operation of emetics upon physiological grounds, as it does, in the same way, the supposed miracle, implied by the expression, " and his sweat was, as it were, great drops of blood falling down to the ground." In this case the emo tions were peculiar and violent, and operated in their compound aspect, according to the explanations which occur at p. 631, § 8923 b, and ut supra. See, also, Nervous Power, MENTAL EMOTIONS, ANALOGIES, CAP-ILLARIES, EMETICS, and SWEAT. Also, other facts and illustrations relative to the secretion of blood by the skin, piamater, &c., in Medical and Physiological Commentaries, vol. i., p. 371-384 (pathology of spontaneous hemorrhage); p. 683-690, (endosmose and exosmose); vol. ii., p. 546-566, (philosophy of spontaneous hemorrhage.)

SUPPURATION,

a result of inflammation, instituted for great final causes, p. 471-474, § 730 -733 ; p. 546-551, § 862, 863

variable according to the exact condition of pathological states, p. 478-480, § 740, 741; p. 484, § 748; p. 536-539, ◊ 847 c-848.

occurs, in a special product, upon mucous surfaces without ulceration, and farther illustrative of final causes, p. 472, § 733 a.

SWEAT,

an excreted product, p. 230, § 420-422. considered in its relation to disease, p. 451, 452; and to physiological influences, see Suporifics, and Ex-CRETION.

coincidence between, and mucus and carbon, as products of organization, p. 230, § 420. See, also, Mucous Tissue.

SYMPATHETIC INFLUENCES,

laws of, p. 55, § 113, 115, 117; p. 56, § 120, 124; p. 57, § 125; p. 58, 59, Sympathetic Influences-continued.

§ 129; p. 63-66, § 137-143; p. 67, 68, § 149–152; p. 106–111, § 222– 2333; p. 321-341, § 495-514; p. 405 -412, \$638; p. 661-689, \$894-905; p. 692, 693, \$914-921; p. 698, 699, \$929-935; p. 702-711, \$939-952; p. 746, \$990\frac{1}{2}a. See, also, \$\text{Sympa-}

depend, in part, upon the nature of tissues, p. 64, § 140-142; p. 67, § 150-152; p. 73, § 163. See, also, TISSUES.

SYMPATHETIC NERVE,

pervades all parts, p. 54, 55, § 111, 113; p. 58, § 129; p. 284-289, § 454-4613.

its ganglia to be regarded as analogous to brain, especially in inferior animals, and as contributing to generate the nervous power in the higher orders, p. 55, \Diamond 113; p. 321, \Diamond 497; p. 346, \Diamond 516 d, Nos. 8, 9; p. 349, 350, \Diamond 520–523; p. 353, \Diamond 524 d.

its prolongation through the chain of ganglia consists truly of communicating branches; thus making the ganglia so many intimately connect-

ed centers of sympathy; ibid, &c. its ganglia, plexuses, &c., the media of contiguous sympathy, and more or less of remote, in the higher animals, § 473 c, 497, 516 d, Nos. 3, 4, 5, § 520, 893;—the only centres of sympathy in the inferior animals, ut cit.; ganglia shown to be centres of sympathy by their resemblance to brain; -shown by the ramifications, and the interchanges of their nerves; -shown by the absence of brain and spinal cord in all but the higher an-

imals; ut cit., and passim.
this nerve subserves the functions of organic life, maintaining through reflex actions their harmonious relations, supplying an exciting and modifying influence, and thus also promoting the secretions and exalting the vital states of organic compounds, and supplies the stimulus to muscular fibre in organic life, δ 113–117, 221½, 224–226, 233½, 259, 261, 264, $409 \ k$, $455-461\frac{1}{2}$, $473 \ c$, $475\frac{1}{2}$, $478 \ b$, $488\frac{1}{2}$, 489, 490, 493 cc, 497, 500 g, m, 514 f, 516, Nos. 3, 4, 5, 520, 523-524, $647\frac{7}{2}$, 746 c, 893 a-e, $893\frac{1}{2}$, 902 e-h, 904 bb, 905 a, 939 f, 942 b, 1059.

SYMPATHETIC RELATIONS,

such as are natural, § 129, 137., &c. morbid, p. 59, § 129 i; p. 64-66, § 140 ADAPTATION, LAW OF. -143, 147.

SYMPATHIES, MORBID,

of the Individual Tissues; see Tissues. of the Compound Organs; See ORGANS, COMPOUND.

SYMPATHY,

its general consideration, p. 283-362, 452-530; p. 412, $638\frac{1}{2}$.

of three kinds, continuous, contiguous, and remote, p. 321-335, § 495-511.

contiguous and remote depend upon the nervous power, operating in its connection with sympathetic sensibility, ibid. See, also, Nervous Power, and Sensibility, sympathetic.

continuous, common to plants and animals, p. 322, 323, § 498; p. 351, § 524 a, No. 2.

its main centers, in the higher animals, the brain and spinal cord, p. 323, § 499. See, also, Sympathetic Nerve, and Nervous Power.

its physiological laws well settled, p.

111. \(234 a.

not applied pathologically or therapeutically, p. 111, § 234 a. See, also, HUMORALISM, and ORGANIC CHEMIS-

its natural conditions neglected or ridiculed, p. 111, § 234 b; p. 283, § 452 b. how far expounded by the Author; see NERVOUS POWER, the Philosophy of

its Operation, &c.

admitted Laws of, and their application, by the Author, to pathology and therapeutics, p. 280-361, § 450-530.

physiological Laws of, luminously expounded by the great Prussian Physiologist, p. 341, § 514½ b; p. 362, § 530

SYMPTOMS,

the index of disease, p. 434-445.

certain special ones, p. 442-445 mode of investigating, p. 430-433, § 675, 676 a; p. 437-442, § 685, 686; p. 561, § 888 a.

SYNCOPE,

produced, not as supposed, by deficiency of blood at the center of the circulation, or by privation of nervous influence, but by a strong determination of the nervous power upon all the organs of circulation; reproduced by the antecedent enfeebled action of those organs, p. 304, 305, \lozenge 481 g, h; p. 703-709, \lozenge 940-951.

removed by the action of the nervous power, or by irritating the heart mechanically, p. 89, § 188 a; p. 107, 108, § 226, 227; p. 705, § 945.

TABLES,

of Organs according to their relative functions, p. 57, § 125.

of Tissues in their order of liability to inflammation, p. 70, 71.

of Tissues as to force of disease, p. 72. of Tissues inflamed, as to treatment, p 72, 73.

975 INDEX.

INDEX II.

A.

ACCLIMATION,

philosophy of, p. 364-366, § 544-556; p. 425, § 664, 441½ b, 1047.

the same philosophy concerned in the exemption from repeated attacks of intermittent and yellow fevers, &c., as respects small-pox, measles, scar-Nevertheless, the sublatina, &c. jects of the former must continue to reside in the malarious climates, or the original susceptibility will return, p. 364–366, § 544–556; p. 425, § 664. 665. SELF-LIMITED DISEASES, Index II.

It is more owing to abstemious habits than to any peculiarity of Constitution that the Negro escapes yellow fever, &c., more than the white population, who may be equally acclimated. The indulgences of the latter render them more susceptible of the morbific action of the essential predisposing cause, and act as exciting causes when the system is predisposed to the disease. The reverse of this happens with the malignant cholera, since in that affection, vegetable food, excepting the simplest kind (and fruits also), is the principal exciting cause. Mulattoes are said by some to be more liable to yellow fever than the Negro, and, where that is observed, it is because their habits are more luxurious; not because, as has been assumed, they are impregnated with the blood of the white man. It is a full, not an empty stomach, that aids in breeding pestilence, p. 251.

Absorption, see Ind. I. Hum. Pathol., II. Adaptation, Law of. See Index I.

AGE, ADULT,

begins at the age of twenty to twentyfive years, and reaches to about sixty years, p. 380, § 579 a—from the end of Youth to the end of Manhood there are but few changes of organization or in the vital endowments, but the Passions are now in greatest opera-tion, and supply a fruitful evidence of the existence of a self-acting Principle, distinct from the bodily structure, and of its influences in laying deeply the foundations of disease. Nevertheless, some new predispositions to disease spring from the organic constitution peculiar to this age, espeAge, Adult—continued.

cially in the female, p. 381, § 579 b; p. 865-868, § 1067. Also, Mental Emotions, and Remedial Action, subdivision Mental Emotions, Index II.

AGE, OLD,

divided into three stages, extending from sixty to eighty-five years and upward, p. 382, § 580—changes in organization are now taking place through which the Organic Properties are inflicting death upon themselves, though morbific causes operate with a diminished intensity, corresponding with the waning activity of Organic Life; the Passions are comparatively powerless, and the Mind is gradually going with the Organic Functions. Remedies are, therefore, less energetic, nature less recuperative, and, for like reasons, art must be prompt and efficient in proportion to the exigencies of declining nature, p. 382–383, ◊ 581 b-584; p. 401-402, § 633; p. 768-770, § 1014-1017.

AGE, STAGES OF

the periods which mark the times when the greatest physiological changes take place, with corresponding fluctuations in disease and in mental characteristics-all depending upon natural modifications or mutations of the Vital Properties and Functions, p. 373, § 574, 575. Remedial Action, subdivision MENTAL EMOTIONS, Index II.

two methods of treatment by, the moderate and excessive, one regarding the recuperative law, the other relying wholly upon the drug, and their results considered, p. 596-604, § 892 b-k.—Notes K p. 1119, L p. 1120. CIRCULATION OF THE BLOOD—continued

from Index I. See VEINS, Index II.

a right estimate of the powers which carry on the circulation important in philosophical and practical medicine, p. 208, § 382; p. 214-215, § 393-396 prevailing errors in regard to it prolific of evil, p. 208, § 383; p. 215, 6 394.

Author assigns seven elements, which concur harmoniously together, p. 209,

§ 384; p. 934, § 1090.

Author shows an exquisite vital consent of action of veins with the arteries through reflex influence of cerebrospinal and ganglionic systems, "not less so than the iris with the retina" excluding the mechanical doctrine, p. 210, § 389; p. 215, § 394, 395; p. 216, § 399; p. 286, § 456 a, b; p. 340, § 514 k; p. 827, § 1056, p. 503, § 794.

venous circulation determined principally by derivative power of the right cavities of the heart, and the arterial through the pulmonary veins by the left cavities; but a propelling power of the arterial capillaries is indispensable, assisted also by the muscular power of the veins, p. 210-211, § 388, 389, 390 b; p. 212-213, § 392; p. 215, ♦ 396; p. 503, ♦ 794; p. 934, § 1090.

objections answered, p. 211, § 389, 390 b; p. 214, § 392 c.

Author shows that the suction power of the heart is indispensable to the portal circulation, and to that of the lymphatics, lacteals, thoracic duct, and umbilical vein, p. 211, § 390 a; p. 214, δ 392 c, d—and shows that the valves of the veins are always open unless there be a reflux of blood, p. 212, § 391.

the action of the capillary arteries, and the influence of the nervous system upon them, and upon the veins, shown by their natural phenomena and by Exp. by Buniva and Procter, p.

Circulation of the Blood-continued.

216, § 394–399; p. 227, § 411; p. 485, § 750 a, and p. 827, § 1056. Also, Medical and Physiological Commentaries, Article Powers which CIRCULATE THE BLOOD, vol. ii., p. 398-426, where the foregoing subjects are elaborated; and Article THE-ORIES OF INFLAMMATION, p. 141-207.

Coffee,

its modus operandi through alterative action of reflex nervous influence as an antidote for poisoning by opium, and illustrated by analogous effects of cold dash through the same influence, p. 338, § 514 d; p. 592-593, § 891½ k; p. 737-738, § 984 b. Cold, Shower Bath, &c.,

employed to illustrate the reflex action of the nervous system in the production and cure of diseases, whatever part may be the seat of the direct action of remedial and morbific agents, and to show how readily and variously the nervous influence is modified in its nature, and how, as rendered thus alterative of organic actions, it readily lights up diseases, or proves the direct efficient means of curebeing equally true of mental emotions according to their nature as of physical causes, p. 107-112, \(\) 227-234 \(b \); p. 230, \(\) 422; p. 245, \(\) 440 \(c \); p. 253, \(\) 441 \(d \); p. 323-324, \(\) 499-500 \(c \); p. 338, \(\) 514 \(d \); p. 339-341, \(\) 514 \(g - m \); p. 359, \(\) 527 \(b \); p. 360, \$ 527 \$\delta\$; p. 416-417, \$ 649 \$c\$; p. 421 -422, \$ 657\$; p. 661-663, \$ 894-896\$; p. 670-671, § 902 m; p. 880, § 1074. Also, Skin; Causes, Morbific, Index II; p. 580, § 890½ d.

illustrates, also, from its want of astringency, and difficulty of its absorption, the modus operandi of Astringents through alterative influence of reflex action of nervous system, p. 533, § 842; p. 572, § 890 b. Also, last preceding references, and IPECACUANHA. Index II.

COLOCYNTH,

its therapeutical and morbific effects, p 856, \$ 1063.

COMBUSTION, SPONTANEOUS,

of the human body, p. 863, § 1066 a.

CONSTIPATION, HABITUAL,

most successfully treated by small and frequently-repeated doses, and not by full and rarer doses, of catharticsthe reflex nervous influence being mildly maintained in the former case, while it is abrupt and violent in the latter, p. 366, § 556 b, and references there; p. 567-569, § 889 l-mm. Also, ALTERATIVES, CATHARTICS, EXER-CISE, Index II.

Consumption. See Phthisis Pulmona-LIS, Index II.

CONTAGION—continued from Index I.,

subject to the law of limitation in respect to causes of a specific natureshowing that yellow fever, plague, small-pox, measles, and scarlet fever can not be alike produced, in either case, by vegetable miasmata and by the morbid products of living organization. And so, upon the same principle, nothing will change, in a sound constitution, an inflammation of the common kind into a specific form, unless as when a specific virus is applied to a wound or an ulcer, and also unless some specific predisposition, like the scrofulous diathesis, be implanted in the constitution (which is equivalent to a specific remote cause); and each one of the specific causes will produce a particular, and generally well-marked species or variety of the disease. And so of yellow fever, intermittent fever, plague, &c., p. 27, ♦ 52; p. 418–420, ♦ 652–653. CAUSES, MORBIFIC, Index II.

CONVULSIONS,

contrary to the opinion of Marshall Hall, that "all convulsive affections are diseases of the true spinal or excitomotory system;" they are commonly owing to simple irritation propagated from distant parts both upon the brain and spinal cord, and the consequent reflection of an irritating nervous influence upon the voluntary muscles. Hence a division of the gum, or of a nerve or tendon, or a warm poultice to them, or an enema, may at once put an end to the trouble, p. 357-358, § 526 d; p. 590-591, § 891½ b; p. 592-593, § 891½ k.

questions of this nature not to be determined by experiments which do not refer to the nervous system as a whole, p. 287-290, $\frac{4}{5}8-461\frac{1}{2}$; p. 292, $\frac{4}{5}473$ a; p. 296, $\frac{4}{5}476$ c; p. 303, $\frac{4}{5}481$ e, f. Also, Mental Emotions, Index II.

nevertheless, diseases of the brain and spinal cord are apt to give rise, both by direct and reflex action, to great disturbances in the organs of organic life, and the Passions, through the intercommunication of the cerebrospinal and sympathetic systems, may produce convulsions, as in hysteria; though not so diseases of the nervous centres, unless they result in effusion or disorganization, p. 334, §

how relieved by Antispasmodics through reflex action of the nervous system. See Antispasmodics, Index II.

COTTON WOOL,

a sedative, and curative of inflammations and ulcers, p. 833, § 1057 k.

COUNTER-IRRITANTS,

belong to Author's eighth order of Antiphlogistics, and consist of Vesicants, Rubefacients, Suppurants, Escharotics, Potential Cauterants, Actual Cauterants. Other groups belong to this order of Local Applications, p. 642-644, § 893 a, b.

vesicants the most important, but mostly limited to the genus Cantharis, p. 644,

♦ 893 c.

all may operate upon internal parts through alterative influence of reflex action of nervous system; but many of them are commonly local only in their effects. Whenever they exceed the limit of local action, it is through reflex nervous influence, and this influence, especially in the case of vesicants, instead of being curative, may produce or aggravate disease, according to existing susceptibilities and the natural endowment of tissues and organs, and throw the whole body into universal commotion -by which is exemplified the close analogy between remedial and morbific agents, and, as demonstrated (articles Cantharides, Seton, Cold, &c., Index II.), that remedies do not operate by absorption, but through alterative action of the nervous influence, and according to the nature of the remedy or mental emotion and the existing susceptibilities of organs that may arise from disease, &c , p. 338, § 514 d; p. 359-360, § 527 b; p. 592, \$891½ g; p. 642-659, \$893 a-q; p. 679-681, \$905 a; p. 850, \$1059; \$1088. Reflex Ac-TION OF NERVOUS SYSTEM, REMEDIES; CAUSES, MORBIFIC; MENTAL EMO-TIONS, STRUCTURE, Index II.; NERVous Power, Index I. and II.

introductory review of problems relative to the operation of other remedies through alterative action of reflex nervous influence to facilitate an understanding of the same modus operandi of Counter-Irritants, which opens widely a view of the Author's principles relative to vital solidism, and direct and reflex action of the nervous system in the production and cure of disease, p. 645-646, § 893 c, d.

their immediate effect strictly morbific, variously modifying the nervous influence, and imparting to it an alterative condition which may be either curative or morbific according to existing susceptibilities, &c., p. 646-658, § 893 c-p. Also, the foregoing references to Index.

| Counter-Irritants-continued.

the artificial inflammation produced by the vesicating plaster either in the skin or the bladder readily subsides, and thus, also, through its development and modification of reflex nervous influence, it institutes such pathological changes in diseased internal organs as to lead to their speedy cure -thus illustrating the morbific nature of positive remedial action and its distinction from the effects of more profoundly morbific causes, that remedies cure by substituting new and transitory pathological conditions, and the great recuperative law of Nature; and which is farther shown by the manner in which the plaster of Cantharides will arrest erysipelas, and the oil of turpentine relieve scalds, p. 646-647, \$ 893*c*-*e*; p. 652, §893*l*; p. 682, §905*b*.

the foregoing quick subsidence of the artificial inflammations illustrates, also, the principle involved in the spontaneous subsidence of the self-limited diseases; for, however profoundly their morbific causes may operate, they carry with them the virtues which administer to the recuperative law, and are on common ground with remedial agents when these give rise to inflammation, p. 544-545, § 853; p. 850, § 1059.

Also, Remedies, Remedial Action; Diseases, Self-limited; Index II.

their curative and morbific effects upon deep-seated parts refute the doctrine of the operation of remedies by absorption, and confirm the Author's doctrine of the alterative influence of reflex action of nervous system, p. 338, § 514 d; p. 347, § 516 d, Nos. 12, 13; p. 642-647, § 893; p. 679-681, § 905 a; p. 850, § 1059 a, 1088.

the cutaneous effusions to which they give rise not instrumental, p. 648, § 893 f; also, Sweat, Index II.—nevertheless, full vesication, like active purging, is often indispensable; and there is a great difference in the results of simple Rubefacients and vesication by Cantharides, ibid., and p. 564, § 889 b; p. 565, § 889 f-which difference is owing, in part, to the difference in the virtues of the remedies, and in part to the difference in time, as seen particularly in vesication by Cantharides and scalding water, and in the difference in results in the treatment by one or the other of acute and chronic inflammations-and by the whole of which is illustrated the philosophy which concerns the vast difference between a sudden and gradual development of reflex nervous influence

Counter-Irritants—continued.

of a deleterious nature, as seen, in the former case, in the fatal effects of blows upon the epigastric region, the shock of surgical operations, and the violent passions, hydrocyanic acid, tartarized antimony, a large abstraction of blood, p. 648, \lozenge 893 g ; p. 650–651, \lozenge 893 i. Also, p. 296, \lozenge 476 c, 476½ b ; p. 298–299, \lozenge 476½ h–477 a ; p. 300, § 479; p. 304, § 481 g; p. 319–320, § 494; p. 334–336, § 509–511; p. 523–524, § 827 d; p. 525, § 828 b, c; p. 661–663, § 894–896; p. 703–711, § 940–952; p. 726, § 961.

opposed to the sudden and violent operation of counter-irritants, &c., as last considered, is the gradual and persistent development of reflex nervous influence as manifested by small and frequently repeated vesications, and by setons and issues, in treating chronic inflammations—the decision being in favor of the first remedy, p. 648-649, § 893 g, h; p. 679-681, 905 a-it being the same, also, in the case of small and repeated leechings, p. 696-697, § 926, 927 a. Also, Alteratives, Leeching, *Index II*.

the extent and part of the surface vesicated, and the intensity of the artificial inflammation, and the time of application, as it respects antecedent means, are, as with other remedies in their appropriate use, important considerations, p. 649-652, § 893 i-n.

illustrated by effects of natural, reme-

manifested by the Mind and Instinctive Principle, p 369-370, \$ 564-568; p. 894-895, \$ 1078 b. illustrates the instability of the vital

properties, p. 363, § 541. Also, VITAL

PROPERTIES, Index I.

generally results in diminished irritability, but may be the reverse, and either practically important, with illustrations, p. 366–367, § 556 *a-d*; p. 532–533, § 841; p. 567–569, § 889 *l-mm*; p. 585, § 891 f.

always relative to impressions, more or less durable, upon the vital, mental, or instinctive constitution, p. 363, §

540; p. 894–895, § 1078 b.

liable to obtain under the repeated or continued operation of almost all agents capable of affecting the vital or mental properties, p. 364, § 543.

through which miasmata, tobacco, crude food, &c., cease to be injurious, p. 364, § 544. Also, Acclimation, Index II. or may obtain from one application of particular causes, so as to render them

inoperative afterward, p. 364, § 545. lessens or increases the susceptibility of organs to the action of remedies, p. 364, § 546; p. 532–533, § 841; p. 542, § 854 c, d; p. 665, § 901.

demonstrates the operation of remedies and morbific causes by alterative influence of reflex action of the nervous system, p. 364, § 547; p. 532-533, § 841; p. 649, \$ 893 h.

its effects generally most prominent in organic life when causes are long in operation-a law of great practical

bearing, p. 364, § 548 a, b

not much applicable to food and other perfectly natural stimuli—showing Design; though some kinds liable to, p. 364-365, $\delta 548\frac{1}{2}$ a, b.

Habit, Vital-continued.

follows, in respect to morbific and remedial agents, the law which governs the relative duration of disease when produced by remedies and truly morbific causes, p. 365, § 549-554; p. 366, § 555; p. 542, § 854 c-d, p. 665, § 901. Also, Cantharides, Counter-Irri-TANTS. Index II

illustrated by the tolerance of frequentlyrepeated and increased doses of medicines, and its subsidence on their suspension for a short time, p. 364, \$ 543; p 365, \$551, 552, p. 532-533, \$841; p 569, § 889 mm; p. 649, § 893 h.

its effects vary according to the exact nature of its causes, p. 366, § 553. allied to the principle which lies at the foundation of disease and its cure, p

366, § 555, p 542, § 854 c-f liable to be influenced by accidental causes, and to thus affect the treatment of disease, with examples, p

367, § 556 *d*-557.

embraces the cumulative effect of remedies, and predisposition to disease, with illustrations, p. 368, § 558 a, b, 559; p. 568-569, § 889 m, p. 669-670, § 902 i; p. 675-676, § 904 b Also, Predisposition, Remedies, In-

dex II.

relates to the tenacity of many diseases, p 368, \$ 560-and to many acquired natural habits of the constitution, o 561-and to luxuries and customs, § $539 \ a, 543, 548 \frac{1}{2} \ b, 562$ —and to the periodical desire of food, and many little usages, § 563—and to the culture of the mind, or of any mental faculty at the expense of others, and to its enjoyments, and to the senses, and to the voluntary muscles, § 543, 564-567-and to analogies between certain special injuries in organic life and of the mind, p 370, § 568; p. 894, § 1078 b

HEART. See HEART AND ARTERIES, In-

dex I.,

constantly influenced, and the arteries also, in all diseases, by reflex action of the nervous system, and the pulse is felt simply for the purpose of ascertaining the extent and nature of these influences, and of thus arriving at the nature and extent of the remote affection, while, also, the heart and arteries do not often fall under the alterative influence of the reflex action so far as to produce disease-employed by the Author, along with many other analogous things, to illustrate the reflex action of the nervous system as the immediate cause of diseases and their cure through its alterative influences upon the organic states, beyond the Heart—continued.

direct seat of operation of remedial and morbific causes-the nervous influence being rendered variously alterative, or simply stimulating or sedative, according to the nature of the causes by which it is brought into any increased or preternatural operation, p. 301-310, § 480-485; p. 355-356, \$\displaystyle{\partial} 526 \ a, b; \ p 443-448, \$\displaystyle{\partial} 687\frac{1}{2}-688; \$\displaystyle{\partial} 714, 715, 961 \ a.

its highly irritable nature employed by the Author to prove that remedies do not operate by absorption, since the most powerful, when swallowed, act mostly upon other parts, and do not often affect the heart, except by reducing diseases upon whose morbific reflex nervous influences the disturbances of the heart depend, § 500 m, $687\frac{1}{2}$, $694\frac{3}{4}$, 826 cc, 829, 893 c, p, 904 c–905 a, 973–975, 1024.

HEAT—continued from Index I.,

applied to the surface, or intestinal canal, by stomach or rectum, and, whether dry or moist, illustrates, like Cold, the operation of remedies and morbific causes through alterative influence of reflex action of the nervous system, and supplies, in its varieties, whether dry or moist, and the different temperatures, from 98° to 120° Fah., a critical illustration of the modifications which the reflex influence undergoes, and through the manner in which it impresses organs favorably or unfavorably, according to their existing susceptibilities, and according to the degree or kind of heat; illustrates, also, the modus operandi of remedial and morbific agents through the same alterative reflex nervous influence, and equally according to the nature and intensity of the agents, and that, although closely allied, our remedies may be curative or morbific according to their exact nature and dose, p. 246, § 440 e; p. 253, § 441 d; p. 351, § 524 a; p. 589, § 891 p; p. 681-683, § 905 a. Also, Warm BATH, COLD, SKIN, FRICTION, FOOD, Exercise, Respiration, Cathartics, Emetics, Index II.

operates in raising the temperature of the surface as a stimulus of organic actions, and without the agency of the nervous system, but will not so influence the reflex action of the nervous system as to raise the temperature of internal organs, nor will cold reduce it unless it impair their functions—a remarkable evidence of Design when contrasted with the manner in which Croton oil, and leeching the anus, will develop a powerful reHeat-continued.

flex nervous influence through the mere propagation of continuous sympathy along the mucous tract of the intestine, p. 249-250, § 441 c; p. 256-259, § 441½-442 e; p. 809-812, \$ 1046-1050. Also, ORGANIC HEAT, Index I. and II.; HYBERNATING ANI-MALS; OIL, CROTON; LEECHING, SUP-POSITORIES, SYMPATHY, subdivision continuous, Index II.

simple warm water, as an enema, among a multitude of analogies in these Institutes, by its development of a stimulating reflex action, and its determination of an exciting effect upon the muscular coat of the intestine and abdominal muscles, shows that if Croton Oil, or other cathartic, be added to the water, the alterative effects of the latter upon remote diseases is through the same reflex influence, now modified by the nature of the added cathartic, and carried by the Author to the interpretation of all remedial and morbific agents beyond their direct seat of operation through alterative influences of reflex action of nervous system, ibid., and Suppositories, Opium (the pill, &c.), REFLEX ACTION OF NERVOUS System, Remedial Action, Index II.; NERVOUS POWER, SYMPATHY, Index I. and II.

HEAT, ANIMAL. See ORGANIC HEAT, Index I. and II.

HEMORRHAGE, SPONTANEOUS,

philosophy of, practically very important -not owing to ruptured vessels, but morbid vascular action, p. 507, § 805; p. 509, \lozenge 812; p. 533, \lozenge 842; p. 572, \lozenge 890 α -h; p. 694, \lozenge 922; p. 738–739, \lozenge 984 c-985; p. 770–772, \lozenge 1018–1019. Also, MEDICAL AND PHYSIOLOGICAL COMMENTARIES, Article Pathology of Cerebral Hemorrhage, vol. i., p. 371-384; Article Spontaneous Hemorrhage, vol. ii., p. 546-550.

if what the Author has said of the physiology of Bloodletting and Leeching be founded in nature, it is obvious that the foregoing comparative safety of spontaneous hemorrhage must depend upon a comparatively milder development of the nervous influence when Nature institutes the loss of blood, p. 694, § 922 b-and the interpretation is farther confirmed by the comparatively slight prostration that results from the drain in malignant cholera, prolonged diarrhœa, abscessés, mennorrhagia, &c., with such as is brought about by the continued use of the mildest purgatives.

nature's mode of cure, and often successfully in such quantities as cannot

Hemorrhage, Spontaneous-continued.

be imitated by art, and in such advanced stages of disease that bloodletting is inadmissible, p. 471–472, \Diamond 732; p. 507, \Diamond 805; p. 550, \Diamond 863 f; p. 573–575, \Diamond 890 e-f; p. 770–772, \Diamond 1019; Notes Fr p. 1135, Irp. 1139.

Nature, therefore, concurs with experience in protesting against the use of Astringents to restrain this natural means of cure, unless proceeding to an alarming excess, p. 573-575, § 890 a-h; p. 771-772, § 1019 g, h. Also, "Debility," Index I. and II.

nevertheless, when practicable, as in the early stages of disease, and if the hemorrhage proceed from an important organ, the pathological condition should not be left to Nature, but Art should interfere with its direct Antiphlogistics, especially Bloodletting, Tartarized Antimony, and Vesicants, and this particularly in pulmonary hemorrhage. See foregoing references, and Expectorants, Astrin-GENTS, PNEPMONIA, Index II.

all preternatural effusions are designed for useful ends, and form some of the most remarkable examples of Design. If they take place within cavities or the structure of organs, it is still the same, nor does Nature depart from any great law for the sake of special exigencies, p. 471-476, § 732 b-733; p. 546-547, § 862-863 d; p. 550-551,

δ 863 e-864.

HICCOUGH,

introduced to illustrate the coincidences which attend the operation of the nervous influence, whether brought into action by the mind or by physical causes-presenting an example of a paroxysm brought on by a sense of choking, which was evidently the result of reflex nervous action induced by gastric derangement, and which had the effect of exciting through mental sympathy the same condition in three others that antispasmodics failed of removing, but which was overcome in all the cases by a mustard emetic-thus illustrating, as in hysteria, the modus operandi of an emetic in arresting the paroxysms through the development of another series of reflex actions and the introduction of movements in other associated muscles, though most successfully in the mental cases whose causes were more transient-and illustrating the difference in the modes in which antispasmodics and emetics relieve spasmodic affections through the agency of reflex action of the nervous system, and the differences among other things to the Hiccough—continued.

same effect (as may be seen in the references below) - and illustrative of the delicate shades in variety in which mental emotions modify the nervous influence, and how, through their medium, the mere disgust arising from the thought of taking an emetic will develop the nervous influence so as to stop a paroxysm of hysteria without vomiting, and contrasted with the effect of an emetic in overcoming the same, and with the united effect of disgust in other cases as brought on by the recollection of a former occurrence of the same nature-while the whole, in all its wonderful relations to the mind in its endless variety of demonstrations upon the organic mechanism through its direct development and diversified modifications of the nervous influence, and the perfect correspondence in these respects with the effects of physical agents applied to the nervous centres, or as they may be affected by disease, and thus develop the nervous influence in a direct manner, or as other physical causes give rise to reflex action, and, in all the cases, modify the nervous influence in a manner analogous to the various mental emotions, not only reflect a flood of light upon the modus operandi of all morbific and remedial agents, but, through the foregoing analogies between the mental and physical causes, declare the substantive existence and self-acting nature of the Soul, p. 337-338, § 514c. Also, HYSTERIA AND HICCOUGH, CONVUL-SIONS, WHOOPING-COUGH, ANTISPAS-MODICS, EMETICS, DISGUST, FEAR, MENTAL EMOTIONS, SOUL AND IN-STINCT, REMEDIAL ACTION, REFLEX ACTION, Index II.; NERVOUS POWER, SYMPATHY, Index I. and II.

"cheer up the patient, and he is sure to do well," or, as Hippocrates has it, "he doeth the best cures in whom most trust"-who can mistake an antagonistic substantive cause-something more than imaginary—acting in opposition to itself, when grief, disappointment, despondency, despair, lay deeply the foundations of disease, but rarely too deeply for the mastery of Hope-who can mistake a common substantive, self-acting agent, known as the Soul, which develops and modifies, according to the nature of each emotion, another agent known as the nervous power, or nervous influence (no matter which), upon whose alterative effects, and as it may be rendered Hope-continued.

morbific or curative by the Spiritual part, all the astonishing variety depends; and who so unjust to his reason as not to concede an exact analogy between the modus operandi of these and other emotions, and of all physical causes, whether morbific or remedial, and thus embrace the operation of the whole under a common philosophyor, reasoning from the latter to the former, equally concede the instrumentality of the nervous influence in the former case, and its development by an agent of the same substantive existence as the physical causes, p. 107-111, $0227-233\frac{3}{4}$; p. 324, 0500; p. 333, \(\) 503; \(p. \) 534, \(\) 844; \(p. \) 661-664, \(\) 894 \(b \) 900; \(p. \) 667, \(\) 904 \(c; \) p. 865-868, \(\) 1067; \(p. \) 879-882, \(\) 1074-1075; \(p. \) 886-891, \(\) 1077. as special objects in the treatment of disease, and the difference in the practical habits of the Humoralist and the Vital Solidist, p. 356, \S 526 c; p. 540, \S 851; p. 550, \S 863 e.

HUNGER,

like the exciting cause of Respiration, a Seton, Cold, &c., incapable of being "absorbed"—associated with the physiology of respiration and the influences of food in developing a reflex action of the nervous system, to illustrate the modus operandi of morbific and remedial agents upon parts beyond their direct seat of operation through an alterative influence of the reflex action corresponding with the nature of the exciting causes—the analogies

Hunger-continued.

being, that in respiration the point of departure for the reflex nervous influence is the mucous tissue of the lungs, and that of food, in the examples presented, and of hunger, the mucous tissue of the stomach, while all the remote influences of either are conducted through the nervous system, but with the difference that the reflex action of the nervous system, in the case of respiration and food, is natural and salutary, while in that of hunger, when prolonged, it is morbific-and the analogies between the examples of food and hunger are farther continued in their equal development of reflex action of the nervous system and in the co-operation of mental emotions that develop a direct nervous influence, which, in one case, falls upon the salivary glands with a salutary effect, while it is morbific in the other, and by which is also illustrated the modifications which the nervous influence undergoes according to the nature of the causes which bring it into operation. See Food, THIRST, REFLEX ACTION OF NERVOUS SYSTEM, REMEDIAL ACTION, MENTAL Emotions, the individual Passions, SKIN, COLD, HEAT, DISGUST, SETON, &c., Index II.; NERVOUS POWER, SYMPATHY, Index I. and II.

HYBERNATING ANIMALS,

employed to illustrate the philosophy of animal heat as a secreted product, and in connexion with reflex action of the nervous system, p. 249, § 441 c; p. 253, § 441 d; p. 255-256, § 441½ a; p. 257, § 442 a; p. 262-263, § 446 a; p. 264-265, § 446 d, 447 a; p. 332, § 500 o. Also, Organic Heat, Index I. and II.

show how intense cold, or merely pricking, may develop in animals of a peculiar constitution a reflex nervous influence that shall prove a stimulus to organic functions, and speedily exalt the temperature of the entire body from 39° to 97° F.—and thus showing, also, that animal heat is on common ground with other secretions, p. 249, § 441 c; p. 253, § 441 d; p. 262—263, § 446 a; p. 264—265, § 446 d, 447 a. its varieties, common and specific-as induced by cold and wounds, forming an example of the first, and by all natural and morbid animal poisons, and all poisons of the Materia Medica, and hereditary predispositions, of the last, p. 419-421, \$ 653 b-655; p. 424, § 661; p. 468, § 721; p. 641, § 8924 i.

is either acute or chronic, but, whichever it be, the general principles of treatment are the same, though modified in its details, p. 469, § 723. Also, BLOODLETTING, COUNTER-IRRITANTS,

EXPECTORANTS, Index II.

nevertheless, there are numerous gradations between acute and chronic, and between common and specific, each series, respectively, approximating each other in some of the modifications, and showing that they all belong to a common family, p. 468, § 722

active and "passive," shown to be essentially the same condition, requiring the same principles of treatment, though generally supposed to be in opposition, p. 486-489, § 753-756.

intermittent, depends upon the causes of intermittent fever, requires the same general treatment as the common form, with probably the ultimate use of Cinchona, or Arsenic, p. 424, § 662 b; p. 487–488, § 756 a, b; p. 605–606, \lozenge 892 p; p. 609, \lozenge 892 $\frac{1}{4}$ c; p. 611–612, \lozenge 892 $\frac{1}{4}$ \hbar , ι ; p. 615–616, $\S 892\frac{1}{2}f$; p. 737–739, $\S 894$ –895.

rheumatic, like the intermittent, demands the direct antiphlogistic remedies, and perhaps ultimately other remedies suited to their specific forms, such as Colchicum, and certain acrids, p. 488 -489, ◊ 756 a, b; p. 561, ◊ 888 b; p.

737–739, ◊ 984–985.

scrofulous, another specific form calling for the same general treatment as the two preceding, but more particularly for special remedies like Iodine, Barytes, and, like the rest, illustrate the philosophy of remedial action, &c., phinosphy of 756 a, b; p. 561, \$ 888 b; p. 615, \$ 892\frac{1}{2}e; p. 619-620, \$ 892\frac{1}{2}u; p. 664-665, \$ 900-901; p. 737-739, \$ 984-985. Also, Spe-CIFICS, Index II.

its immediate instruments the terminating series of the arterial system, p. 226-227, § 410, 411; p. 355, § 528 a; p. 483, § 746 a-and why the serous vessels admit the red globules, p. 99, \$ 192-the nervous system locally interested in the results, but in other Inflammation-continued.

respects acts only as an exciting cause of inflammation by direct or reflex action, p. 475, § 733 h; p. 483-484, § 746 c. Also, Reflex Action of the Nervous System, Index II; Nervous Power, Sympathy, Index I. and II.

its proximate or pathological cause consists of two fundamental elements—
1st, an increased action of the vessels;
2d, and by far the most important, a change in kind, § 747, 750-751, 910, 953 d, e. Also, § 384, 399, 410, 485. involves the whole philosophy of all

other diseases, p. 482, § 745.
the prevailing mechanical doctrine of,
which supposes a passive relaxation
of the vessels, and stagnation of blood,
considered, p. 484–485, § 748, 749.

always a local disease, while fever affects the system universally, p. 65, \(\) 143 a, b; p. 66, \(\) 148; p. 417-418, \(\) 650; p. 422, \(\) 657 b; p. 464, \(\) 712; p. 489-491, \(\) 757-760; p. 498, \(\) 784. Also, other distinctions in first subdivision. Also, FEVER, Index II.

nevertheless, inflammation is often complicated with fever at the invasion of the latter, and may be its exciting, though not its predisposing cause, and fever rarely exists long without giving rise to inflammation, of which it may be either an exciting cause in organs already predisposed, or may be the predisposing as well as exciting cause, p. 227, §411; p. 355, §526 a; p. 464, §711-713; p. 481, §743; p. 498, §784; p. 506, §803, 804; p. 508-509, §809-811; p. 510, §813.

the general arterial excitement and heat of skin attendant on inflammation and fever, but which is often absent in both, and always more or less intermitting in the latter, have led to their supposed unity, p. 464, 465, § 713-714. Also, references in first subdivision, and Fever, Index II.

the constitutional excitement of local inflammation is owing to remote sympathy, while that of fever arises from the disease at large throughout the system—the exciting influence of the reflex action of the nervous system, in the former case, being determined especially upon the heart and arteries, while, also, the same phenomenon is most strongly pronounced in inflammation of the brain, when the development of the nervous influence is direct, as in the case of the Passions, but instituting, as a consequence, circles of reflex action, p. 227, § 411; p. 355, § 526 b; p. 465–468, § 714–719; p. 804–805, § 1040, and reference of the service of the control of the

subdivision, Index II.
no "general" inflammation, and the
term "inflammatory fever" hypothetical and objectionable, p. 466, § 716.

farther, the foregoing exciting and alterative influence of reflex action of the nervous system upon the general circulatory system, and its local determination upon individual parts, is the cause of consecutive inflammations, while each one as it comes forward in the progressive series joins in the development of the morbific reflex action, and thus also mutually aggravate each other, and multiply the ratio of the consecutive derangementsand these disturbances of the neverceasing, ever-changing reflex action will depend greatly upon the activity of disease, and upon the importance of the organs and the nature of the tissue affected, though not always so, p. 227, § 411; p. 355, § 526 o; p. 465-466, § 715; p. 467–468, § 718, 719; p. 506–509, § 806–811; p. 511, § 815; p. 679–681, § 904 a; p. 724–727, § 961; p. 730, § 969; p. 731, § 970 c; p. 732–734, § 973–975; p. 804–805, § 1040, and references there. Also, STRUCTURE, REFLEX ACTION; CAUSES, Morbific, Index II.; Nervous Pow-ER, SYMPATHY, Index I. and II.

such is the correspondence among the foregoing influences and derangements, that a modification may be given to the reflected nervous influence by a single remedy, as Bloodletting and Tartarized Antimony (and in fever also, and as complicated with inflammation), that will overthrow all the extensive lesions, p. 65–66, § 143c, and references there; p. 498, § 784 b, and references there; p. 498, § 784 b, and references there; p. 731–732, § 970 c.

produces, also, through the foregoing sympathetic influences, other forms of disease, which concur in modifying the reflex nervous influence, and this often depending upon the special vital constitution of tissues and organs, p. 467, § 718. Also, STRUCTURE.

the development and modification of the reflex action of the nervous system, and its influence upon one part or another, depends, more or less, not only upon the special vital constitution of tissues and the relations which they bear to compound organs as one or another may be the seat of inflammation, and more or less so as it respects

Inflammation-continued.

the determination of the morbific influence upon different parts, but its influence when resulting from venous inflammation is a strong exemplification of the special modes in which the alterative influence of reflex nervous action is modified by the nature of a tissue when affected by a common form of disease, and serves to illustrate the great fact that every cause, both physical and mental, that may bring it into operation, imparts to it a special modification peculiar to its own virtues, p. 444-446, 688 c, f; p. 506-509, \$806-811; p. 511, \$815; p. 724-726, \$961; p. 730, \$969; p. 731, \$970 c; p. 732-734, \$973-975. Also, Structure, Index II; 975. Also, STRUCTURE, Index II.; NERVOUS POWER, Index I. and II.; VENOUS CONGESTION, VENOUS TISSUE,

develops a reflex action of the nervous system which imparts to the pulse its peculiar characteristics of hardness and incompressibility, and the peculiar modification of the nervous influence as instituted by inflammation is farther manifested in its production of those changes of vascular action that lead to the buffing and cupping of abstracted blood, while, on the other hand, this protean power may be almost instantly made to change its shape and establish a totally new order of things under the loss of blood or a mental emotion, p. 227, § 411; p. 355, § 526 a; p. 444-445, § 688 a-f; p. 708-710, § 951-952 b; p. 804-805, § 1040, and references there.

develops an exciting nervous influence which sustains the system under the loss of blood, though of some tissues, and in their connexion with compound organs, more than others, while the loss of blood so modifies the alterative influence of the reflex nervous action (and upon which all the phenomena of Bloodletting depend) as to speedily change the whole condition, p. 732-736, § 973-980. Also, p. 70-73, the Tables; p. 227, § 411; p. 355, § 526 a; p. 444–446, § 688 d; p. 506–509, § 806-811; p. 511, § 815; p. 709-710, § 952; p. 724–734, § 961–976; p. 735–736, § 978–980; p. 804–805, 1040, and references there. Also, BLOODLETTING, LOSS OF BLOOD, REFLEX ACTION, ANTISPASMODICS; BRAIN, INFLAMMATION OF; STRUC-TURE, Index II.; NERVOUS POWER, SYMPATHY, Index I. and II.; VENOUS Congestion, Venous Tissue, Index I. when affecting the brain, the exciting

nervous influence is greater than of

Inflammation—continued.

other organs, and here, too, the nervous influence is developed in a direct manner, and the motor nerves are alone concerned; but as soon as felt by other organs, they react upon the nervous centres, and give rise to circles of reflex action, p. 671, \$903; p. 733-734, \$974 c-975. Also, VENOUS CONGESTION; BRAIN, INFLAMMATION OF; MENTAL EMOTIONS, the individual Passions, Index II.

when affecting any important organ in small-pox, measles, and scarlet fever, it gives rise to such alterative influences of the reflected nervous action as enables the system to bear the remedies that would be necessary when the same disease occurs independently, and which might be otherwise fatal, p. 59, \$\displays\$ 129 \$h\$, \$i\$; p. 61, \$\displays\$ 134; p. 63, \$\displays\$ 137 \$b-e\$; p. 65, \$\displays\$ 143 \$c\$; p. 67, \$\displays\$ 150-151; p. 69, \$\displays\$ 156 \$b\$; p. 73, \$\displays\$ 163; p. 227, \$\displays\$ 411; p. 355, \$\displays\$ 526 \$a\$; p. 538-539, \$\displays\$ 847 \$g-849\$; p. 542-543, \$\displays\$ 854 \$f\$; p. 544-545, \$\displays\$ 858; p. 804-805, \$\displays\$ 1040, and references there.

all the foregoing influences of reflex action of the nervous system are examples of that alterative action as brought into operation by all remedial and morbific causes, physical and mental, whenever they act upon parts beyond the seat of their direct operation, though variously modified according to the nature of the exciting cause, and are the medium through which all the remote changes in the solids and the fluids (the blood included) are brought about, p. 483–484, § 746 c; p. 679–681, § 905 a. Also, Blood-LETTING, LOSS OF BLOOD, CATHAR-TICS, EMETICS, &c.; CAUSES, MOR-BIFIC; REMEDIES, THERAPEUTICS, RE-MEDIAL ACTION, SECRETION AND Ex-CRETION, REFLEX ACTION OF NERVOUS System, Mental Emotions, the individual Passions, &c., Index II.

illustrates the manner in which, like compounded remedies, a compound Passion will so modify the reflex action of the nervous system as to affect the secretions in a different manner from either of the individual agents, Jealousy-continued.

and which furnished a theme for Sappho, p. 631, § 892\frac{3}{2} b. Also, p. 90-95, § 188\frac{1}{2} d; Shame, Secretion and Excretion, Index II.

JOY AND ANGER,

the Passions which destroy life suddenly by a sudden and violent determination of the nervous influence upon the brain, and, through that organ, upon the heart, &c., after the manner of blows upon the epigastrium-demonstrate Author's theory of the operation of remedial and morbific agents through alterative influence of reflex action of nervous system-contradict the physical hypotheses-and contribute in establishing demonstration of the substantive existence and selfacting nature of the Soul, p. 95, § 1881; p. 107–111, \(\delta 227–233\)\{ \cdot\}; p. 284–286, \(\delta 455-457; p. 298, \delta 476\)\{ \cdot\}; p. 306–302, \(\delta 478-480; p. 326-329, \delta 500 \)\{ -n; p. 334–335, \delta 507–511; p. 362, \delta 634; p. 670, \delta 902 \)\{ p. 704, \delta 944 \} a; p. 707, § 947; p. 709, § 951 b-d; р. 865–868, § 1067; р. 879–881, § 1074; р. 887, § 1077. Also, Sтом-ACH, BLOWS UPON, and the several references to Articles under JEALOUSY, Index II.

consider, also, their milder operationhow Joy lights up every feature, gladdens the heart, and invigorates digestion; or Anger thumping at your side, but differently from Fear, injecting the face, while Fear blanches it, protruding the fiery eyeballs, though not after the manner of Fear, and imparting herculean strength to the muscles, while Fear paralyzes, and compare with what is said of the development and modification of the nervous influence, both direct and reflex, by physical agents, under Article Gen-ERALIZATION OF REFLEX ACTION OF NERVOUS SYSTEM, Index II. Also, p. 324, § 500 c; p. 326, § 500 g; p. 865–868, 1067; p. 879–882, § 1071–

1075.

K.

KIDNEY,

effect upon, in producing saccharine urine, by pricking medulla oblongata, p. 792, § 1032 d.

its diseases, treatment of, p. 450, 451,

♦ 691; p. 847, ♦ 1058 s.

the reciprocal sympathies between the skin and kidneys, in their natural condition, through reflex action of the nervous system, evince the great liability of the nervous influence to disturbances from slight causes, and, Kidney-continued.

like the physiology of respiration, supply a key to the whole philosophy of the operation of remedies and morbific causes upon all parts beyond the seat of their direct effects through alterative influence of reflex nervous action - while, also, the torrent of urine which is often generated by the contact of cold air with the surface, and its sudden expulsion from the bladder by the cold dash or by the warm bath, supply a simple element of the universal instrumentality of the reflex nervous influence in inducing disease and of changing the condition of morbid states, and of the secreted products, according to the manner in which the nervous influence may be modified by remedial and morbific agents-and taking along, also, the exactly corresponding effects of Fear, Loss of Blood, &c., in suddenly augmenting the urine and perspiration, and in inducing purging and convulsion of muscles, we reach the certainty that these effects of the latter are, equally with the former, owing to the exciting and alterative influences of that same protean power, and that it may be brought into direct operation as well by causes acting directly upon the nervous centres as when it involves both orders of nerves, p. 107-111, § 227-233\(\frac{1}{2}\); p. 230-233\(\frac{1}{2}\); p. 242-427\(\frac{1}{2}\); p. 284-287\(\frac{1}{2}\); d. 455-459\(\frac{1}{2}\); p. 290-291\(\frac{1}{2}\); d. 462-470\(\frac{1}{2}\); p. 295-321\(\frac{1}{2}\); d. 476-494\(\frac{1}{2}\); p. 321\(\frac{1}{2}\); d. 496\(\frac{1}{2}\); p. 631-632\(\frac{1}{2}\); d. 892\(\frac{1}{2}\); p. 651-653\(\frac{1}{2}\); 6. 894-896\(\frac{1}{2}\); p. 651-673\(\frac{1}{2}\); 6. 903-904\(\frac{1}{2}\); p. 675-676\(\frac{1}{2}\); 6. 903-904\(\frac{1}{2}\); p. 675-676\(\frac{1}{2}\); 9. 903-904\(\frac{1}{2}\); p. 675-676\(\frac{1}{2}\); 9. 903-904\(\frac{1}{2}\); 9. 903-904\(\frac{1}2\); 9. 903-904\(\frac{1}2\); 9. 903-904\(\frac{1}2\); 9. 903-904\(\fr 665-676, ◊ 902-904; p. 679-681, ◊ 905 a. Also, Reflex Action of NERVOUS SYSTEM, MENTAL EMO-TIONS, FEAR, and the other individ-ual Passions, Weeping, Skin, Cold, Heat, Warm Bath, Respiration, CONVULSIONS, SPASMODIC AFFEC-TIONS, WHOOPING-COUGH, FOOD, LOSS of Blood, Bloodletting, Secretion AND EXCRETION, Index II.; SYMPA-THY, NERVOUS POWER, Index I. and II.

not a "strainer," as commonly supposed, \$\langle \text{23-10-84}\$, \$\frac{1}{4}\$ commany supposed, \$\text{p. 222-227, \$\delta 409 c-411; p. 230-233, \$\delta 422-427; p. 318, \$\delta 493 d; p. 631-632, \$\delta 892\frac{2}{3}; p. 788, \$\delta 1032 a; p. 801, \$\delta 1036; p. 910-911, \$\delta 1083, and confirmed particularly through the last

preceding references.
its modified action, as denoted by fluctuations of the urine, generally owing to diseases of other organs, especially of the digestive, and induced by reflex action of the nervous system, which disturbs its functions without inducing absolute disease, when the urine

Kidney-continued.

should be regarded as a symptom only, like that of the pulse, or the morbid aspects of the tongue, through which some knowledge is obtained of the nature and force of disease in other parts, p. 232-233, § 426, 427. Also, Pulse, Tongue, Amenorrhæa, Urine, Index II.; Menstruation, Index I. Also, p. 847, § 1058 s.

KIESTINE,

declared, on authority, to be a "pure illusion," p. 787, § 1032 a.

L.

LACTATION,

exemplifies the natural instability of the properties of life, which, in being designed for useful ends, becomes the occasion of diseases and of their cure, p. 3, \(\delta \) b; p. 61, \(\delta \) 133 c; p. 68-69, \(\delta \) 153-156; p. 87, \(\delta \) 160; p. 120-122, \(\delta \) 237-240; p. 352, \(\delta \) 524 d; p. 376-380, § 578; p. 662, § 895. Also, VITAL PROPERTIES, ORGANIC LIFE, Index I.; Youth, Infancy, Vomit-ING, PREGNANCY, Index II.

alterative influence of reflex action of the nervous system, excited by the uterus, the efficient cause, ibid., and p. 111, § 233³/₄; p. 351, ◊ 524 b. Also, Metas-TASIS and REPULSION, Index II.

considered in connexion with the vital and mechanical doctrines of secretion, and as a proof from analogy, along with the now admitted absence of the constituents of the bile in the blood, that the kidney is not a "strainer,' and in its relation, also, to the supposed production of sugar by the liver, p. 783-793, § 1031-1032. Also, the preceding references, and references under Kidney and "Strainage," Index II.

diverted from its natural state, and the milk altered by mental emotions

through direct propagation of the nervous influence, p. 788, § 1032 a, and MENTAL EMOTIONS; BRAIN, IN-FLAMMATION OF; REMEDIAL ACTION, subdivision MENTAL EMOTIONS; the individual Passions, Secretion and Excretion, Reflex Action, Index II.

proof derived from, that sugar does not exist in the blood, p. 785, § 1031 b:

p. 790, § 1032 b. Lacteals, (See Absorption, Index I.) circulation in, depends upon suction of the heart and their own action, p. 211, § 390 a; p. 214, § 392 c, d.

exclude the bile, and all intestinal products excepting chyle, unless diseased, and why—and, for like reason, exclude remedial agents, and not liable to inLacteals—continued.

flammation like the Lymphatics and Veins—all evincing great Design, p. 99, § 192; p. 129–131, § 277–284, and references there; p. 356, § 526 c; p. 632, § 892\frac{3}{2} c. Also, Lymphatics, Veins, Index II. Also, p. 933, § 1089.

allusion to, in connexion with the anatomical relations of the intestinal canal to the nervous system, and Author's doctrine of the operation of Cathartics through alterative influence of reflex action of the nervous system, p. 565. have terminal orifices, p. 933, § 1089.

Liebic's and Carpenter's mechanical doctrine of the function of absorption,

p. 132-133, § 289-292.

LACTIC ACID,

not found in the blood, and physiological conclusions, p. 784, § 1031 b.

LAUGHING,

excited in a direct manner through the Will and Mental Emotion, showing how the latter sometimes conspires with the former in determining the nervous influence upon the voluntary muscles, and may be excited through reflex action of the nervous system, as an ultimate result, by tickling the feet, and may then prove fatal-illustrative of the modus operandi of remedial and morbific causes, physical and mental, through alterative influence of direct and reflex nervous action, and of the substantive existence and selfacting nature of the Soul, p. 323-328, § 499–500 m; p. 707, § 947; p. 709, § 951 b−c; p. 880, § 1074; p. 887, § 1077. Also, MENTAL EMOTIONS, JOY AND ANGER, and other individual Passions; Brain, Inflammation of; REFLEX ACTION, Index II.; SYMPATHY, NERVOUS POWER, Index I. and II.

LEAD, ACETATE OF,

arrests hemorrhage of lungs, uterus, &c., and colliquative sweats, through alterative influence of reflex action of nervous system, since, if absorbed, it would be rendered inert by conversion into another salt, or, if otherwise, the quantity of a grain at a dose, diluted by the mass of blood and other fluids, would not be felt, p. 530, § 837 c; p. 577, § 890 o.

the modus operandi of Astringents and of other remedies illustrated in the foregoing manner, and by other remedial influences of the acetate of lead, and by comparison with other Astringents and with other things, p. 577-578, § 890 o. Also, ASTRINGENTS,

Index II.

LEECHING,

the philosophy of its effects divided into seven stages, p. 692-698, § 914-928.

Leeching-continued.

1st, as in general bloodletting, the first essential effect consists of a contraction of the capillary bloodvessels; but in leeching there is an antecedent vital impression of a very peculiar nature produced upon the extreme vessels to which the leeches are applied, § 915.

2d, an immediate vital contraction of these vessels, arising in part from the foregoing specific impression, and in part from the direct abstraction of their natural stimulus, § 916.

3d, then follows, by continuous sympathy along the vessels (or continuous influence, as the Author prefers, p. 322, § 498 a), and through reflex action of the nervous system, p. 321, § 496, a propagation of the foregoing changes to the entire system of extreme and capillary vessels throughout the body, and why, § 917.

4th, the larger vessels, sooner or later, participate through the foregoing influences (3) in the contraction, φ 918. Also, SΥΜΡΑΤΗΥ, CONTINUE

ous, Index II.

5th, simultaneously, and at an early stage, the heart is brought under the influence of the reflex action of the nervous system, which increases in a rapid ratio, p. 693, §

919; p. 698, § 933.

6th, during the progress of the foregoing influences and changes they become more or less compounded, the reflex nervous influence which is propagated from the extreme to the larger vessels and the heart institutes reflex influences upon the extreme vessels, while these, in being thus impressed, institute an increased amount of the reflex influence upon the heart and larger vessels, which increases still farther the contraction of the small vessels, and this complex or double circle of sympathies continues to advance till the heart becomes overpowered in its action, and syncope takes place, p. 693, § 920, and references there.

7th, the specific artificial impression instituted by leeches at the place of their impression continues to exert a powerful development of reflex action of the nervous system, which is determined with the foregoing effect (2-6) upon the heart and arteries long after the blood has ceased flowing, and, for this reason, the system may be more prostrated by much smaller quan-

Leeching-continued.

tities of blood taken by leeching than by general bloodletting, and syncope may ensue some hours after the blood has ceased flowing, p. 693, § 921 a-c, and references there.—Note Do p. 1132.

direct and reflex action of the nervous system the essential cause of all the effects, ibid., and p. 703-711, § 940-952—and which is distinctly shown by the effect of a single leech in relieving ophthalmia, or pleurisy, or amenorrhæa, &c., when applied to the skin, since there is no vascular connexion between the skin and the internal parts, and the quantity of blood too insignificant to affect the volume of the circulating mass. See BLOODLETTING, GENERAL, Index II.

the effusion of blood is owing to the specific change instituted by leeches in the vital condition of the extreme vessels, being analogous to the process of secretion, and differing totally in that respect from the results of cupping, although in the latter case larger and far more numerous vessels are divided, and then require the aid of an exhausting receiver, p. 694, \Diamond 922 a; p. 702, \Diamond 939 b, c.

hence it is evident that cupping-glasses should not be applied in leeching, and for other reasons, p. 702, § 939 d.

a remarkable difference, also, between the effects of leeching and of spontaneous hemorrhage, which is also analogous to a secretory process, and may amount to many pounds without much impairing the strength or inducing syncope—owing to a difference in the development of the reflex action of the nervous influence in the two cases, p. 694, § 922 b. Also, HEMORRHAGE, SPONTANEOUS, Index II.

other special influences may be obtained through the medium of special vital relations which one organ may bear to another, while the auxiliary part will not only co-operate in the development of salutary alterative influences of reflex action of the nervous system, but may itself be thus relieved of disease more effectually than by any other means-as seen in hepatic congestion, when, if leeches be applied to the anus, or septum nasi, the artificial change which is there established is propagated continuously along the mucous tissue of the intestine and up the duct of the liver into the labyrinth of the organ, while, also, the liver is not only thus relieved and brought to institute salutary reflex Leeching—continued.

action of the nervous system, but the continuous impression upon the intestinal mucous tissue institutes other usefully alterative influences of reflex action, and after the manner of Croton oil applied to the tongue, or of suppositories, p. 694–695, ϕ 923 α –d. Also, p. 64, ϕ 141 b; p. 322–323, ϕ 498; p. 343, ϕ 516 d, No. 2; p. 344–345, ϕ 516 d, No. 6; p. 349, ϕ 520; p. 350, ϕ 523, No. 7; p. 351, ϕ 524 d 7, No. 2; p. 355–359, ϕ 526 d 8, d 9, d 9,

for the foregoing and other reasons, it may be most useful to apply leeches to a part remote from the seat of disease, while in a larger proportion of cases the application should be made near or directly to the affected part, p. 694-695, § 923-924—and the mechanical doctrine of revulsion not to be thought of, p. 695, § 924. Also, Metastasis and Revulsion, Counter-Irritants, Reflex Action of Nervous System, Index II.

again, the best influences will sometimes follow the application to a distant part between which and the seat of disease there are apparently no particular natural relations, as to the feet in amenorrhæa, and the septum nasi in cerebral affections, p. 694-695, § 923 b-924.

operates, in part, upon principle con-cerned in Counter-Irritation, when the reflex nervous influence is developed by the irritation of the skin, p. 659, § 893 q; p. 696–697, § 926, 927 a—and the philosophy considered of the salutary effects of frequent and small abstractions of blood by leeches in chronic inflammation-being, besides the influences peculiar to loss of blood, and by leeching, analogous to the philosophy concerned in small . and repeated vesications in the same conditions of disease, and closely allied in principle to the continued operation of small and repeated doses of alterative medicines, p. 648-649, § 893 g, h. Also, p. 649, \$893 h; COUNTER-IR-RITATION, ALTERATIVES; ANTIMONY, TARTARIZED, Index II.

useful when applied over indolent tumours, and often when not of an inflammatory nature, both by changing the morbid action, and particularly by establishing a susceptibility in the tumours to the local or constitutional action of other remedies, as Iodine, Mercury, Vesicants, &c., p. 659, § 893 q; p. 684, 905½ b; p. 616, § 892½ f.

Leeching-continued.

often useful only after general bloodletting, in chronic inflammations, which demand the sudden and special physiological influences of the latter remedy to overcome the obstinacy of morbid habit, p. 298, § 476½ h; p. 658, § 893 p; p. 697, § 927 a; p. 711, § 953. Also, Bloodletting, General; Habit, VITAL, Index II.—but often beneficial in certain mild, though chronic cases, without the general remedy, § 927 b.

should never precede general bloodletting when the latter may be more useful, as in all cases of severe inflammations, p. 696, § 925; p. 713-714, § 956-958; p. 729, § 966; p. 733, § 974. Also, p. 642, § 892½ ; p. 658, § 893 p; p. 871-872, \$ 1068 d; BLOODLETTING, GENERAL; INFLAMMATION, Index 11.

most sensibly felt in Infancy, and may then be sufficient when general bloodletting would be indispensable at a later age, as the susceptibility to remedial action is then greatest, and a larger volume of blood is abstracted in the ratio of size, and quickly, &c., p. 696, § 925. Also, p. 67, § 150-151; p. 375, \$ 576 e-but never in the cerebral inflammations and congestions of that age, p. 696, § 925 c; p. 733-734, \$ 974 c-975 b. Also, Brain, Inflam-MATION OF; INFLAMMATION, INFANCY, Index 11.

injurious as an early remedy in the grave forms of visceral congestions and inflammations, p. 729, § 965 b, 966.

the nature of its influences considered when excessive, having some peculiarities which differ from the injurious influences that arise from the excessive use of general bloodletting, p. 697-698, § 927 b. Also, BLOOD-LETTING, GENERAL, Index II.
may be a remedy for inflammation in-

duced by excessive general bloodletting, p. 698, § 928; p. 774, § 1024 a. Also, BLOODLETTING, GENERAL, Index

like general bloodletting, more salutary than spontaneous hemorrhages even of large extent, when the remedies may be adopted, on account of, in the former case, the specific influence instituted in the extreme vessels of the bitten part, and the consequent special modification of the nervous influence, and, in the latter, the suddenness of its development, p. 298, § 476½ h; p. 693-694, § 921-922; p. 702, § 939; p. 770-772, § 1018, 1019. HEMORRHAGE, SPONTANEOUS; ERGOT, Loss of Blood, Uterus, Index II. MENSTRUATION. See Index I.

MENTAL EMOTIONS,

see a subdivision, Mental Emotions, under REMEDIAL ACTION, where the references to this subject are numerous, and present a variety of physiological, pathological, and therapeutical problems, illustrative of the Author's doctrine of their action through the direct development of the nervous influence, and of developments of reflex action of the nervous system as consequences of the impressions made upon parts remote from the nervous centres by the antecedent direct development; and also the numerous references under the several subdivisions of Reflex Action of the Nervous System, and of Nervous Power (Index II.), where the analogies with the foregoing are clearly and variously established-each and all of which, certainly their united force, must ere long sweep away those chemical and physical doctrines, which, though promulgated by Genius of the highest order in the walks of Chemistry, and to which mankind are under profound obligations, have, for that very reason, vitiated all Medical Science, and rendered its practice an empirical art. See SHAME, GRIEF, DISGUST, JOY AND Anger, Hope, Fear, Jealousy, Love, 🋊 WEEPING, MICTURITION, LAUGHING, YAWNING, ROOSTING, SNEEZING, MIND, SOUL AND INSTINCTIVE PRIN-CIPLE, CHEMICAL PHYSIOLOGISTS, Index II.; ORGANIC CHEMISTRY, Index I. and II.

bear a strict analogy in effects with those of disease, injuries, and physical irritations of the nervous centres, which develop the nervous influence in a direct manner, and are then alone interested with the system of excitomotory nerves or fibres of compound nerves, and farther establish their analogy with the Mental Emotions through the reflex actions of the nervous system that supervene as consequences of the impressions upon distant parts by the direct development, and other resulting circles of complex reflex actions-whose results declare their dependence upon something, that they are precisely the same in all the cases, and that, therefore, they are equally due to a common cause, and equally so when physical agents acting upon the skin give rise to exactly the same phenomena, and that since neither the external physical causes

Mental Emotions—continued.

nor the brain, nor spinal cord, are transmitted to the affected parts, it is quite logical to suppose that the Mental Emotions are restrained from wandering away from those nervous centres upon which they institute their primary action, and that, if there be any thing of a substantive nature in a blister, or in the stick which inflicts a blow upon the head, and upon which all the distant effects depend, it is equally certain that a substance quite as real, and quite as distinct from the nervous centres, occasions the corresponding results of the mental emotions, and therefore, also, through the same efficient medium-all of which is elaborately apparent in the followis elaborately apparent in the following sections, p. 101–102, § 201–202; p. 107–108, § 227; p. 109, § 230; p. 111, § 233\frac{2}{4}; p. 289, § 461; p. 296, 476 c; p. 302, § 481 b; p. 315–316, § 492; p. 321, § 496, 497; p. 323–330, § 500 a-n; p. 333, § 503–505; p. 336–337, § 514 b; p. 338–339, § 514 d-h; p. 347–348, § 516 d, No. 13; p. 416–417, § 649 c; p. 592–593, § p. 416-417, \$\\$649 c; p. 592-593, \$\\$891\frac{1}{2} k; p. 631-632, \$\\$892\frac{3}{4} b; p. 661 \$ 944 a; p. 707, \$ 947–949; p. 709, \$ 951 b, c; p. 865–868, \$ 1076; p. 874–881, \$ 1071–1075; p. 876–877, \$ 1072 a; p. 886–890, \$ 1077. Also,

the foregoing Articles.
as Mental Emotions, therefore, often give rise to alterative influences of reflex actions of the nervous system, they differ in those respects from the Will, whose displays of the nervous influence terminate in the voluntary muscles, and without exerting any other effect than that of simple motion, and it is alone interested in excito-motory nerves or fibres of that denomination. See WILL, Index I. and II.; NERVES, MOTOR; NERVES, SENSITIVE; NERVOUS POWER, Index I.

do not operate upon the brain or other organs in the metaphysical manner as commonly supposed of all the attributes of the mind, nor according to the doctrine of Chemistry, but in no other conceivable way than as appertaining to a substantive self-acting agent exciting the nervous influence and determining it upon other organs, or upon the nervous centres themselves, according to the exact analogies supplied by all physical causes, and like those, also, modifying the nervous influence according to the nature of the individual emotions-the effects of the Mental Emotions-continued.

Will through the same causation concurring in this demonstration, p. 107–111, § 226–233\frac{2}{3}; p. 266, § 447 d; p. 289, § 461; p. 296, § 476 c; p. 298, § 476\frac{1}{2}h; p. 300, § 479; p. 301, § 480; p. 302, § 481 b; p. 304, § 481 g; p. 306–308, § 483 b; p. 324, § 500 c, d; p. 335, § 511; p. 402–403, § 634–635; p. 534, § 846; p. 606–609, § 947–951; p. 631, § 892\frac{1}{2}b; p. 661–662, § 894 b; p. 745–746, § 990\frac{1}{2}; p. 865–868, § 1067; p. 878–882, § 1074–1075; p. 887, § 1077. since, therefore, according to the foregoing reforement the Metal Terreton of the state of the

going references, the Mental Emotions and the Will develop the nervous influence by their direct action upon the brain, and without the intervention of sensitive nerves, and since, also, the nervous influence, when thus developed by the Passions, brings about precisely the same morbid and curative results as when other things operate through reflex action of the nervous system, it supplies as full a demonstration against any chemical doctrine that may be carried analogically from the supposed positive and negative condition of atoms in the galvanic battery to the double nervous arc; foregoing references, and WILL, Index I. and II.

not only induce and remove disease like all morbific and remedial agents of a physical nature, but, like physical causes, it is one of their most obvious characteristics to determine the nervous influence with such a modifying effect upon the instruments of organic processes as to increase or diminish, or to change the natural condition of the secretions, p. 266, § 447 d; p. 289, § 461; p. 296, § 476 c; p. 302, § 481 b; p. 631-632, § 892‡ b. Also, Fear, Jealousy, and the other individual Passions, Food, Cold, Kidney, Skin, Remedial Action, subdivision Mental Emotions, Index II.

having established the strict analogies between the morbific and remedial effects of the various Passions and all physical agents, and that they are all exerted through the medium of the nervous system, and according to the particular nature and intensity of each one, and that they constantly operate not only in a direct manner through the excito-motory nerves alone, and according to direct physical impressions upon the nervous centres, and according to their nature, but that the Passions, like the physical impressions, through their effects upon organs distant from the nervous cen-

Mental Emotions-continued.

tres, give rise to alterative influences of reflex action of the nervous system according to the nature of each one, and since none but the Materialist will assume that they operate in any chemical or physical manner, we arrive at the incontrovertible conclusion that all the analogous effects of remedial and morbific agents of a physical constitution are not only carried on through the same causation, but that they are equally destitute of all relation to physics and chemistry, ut supra, and the individual Passions, BLOOD-LETTING, LOSS OF BLOOD; BRAIN, INFLAMMATION OF, Index II.

an apparently endless variety of problems are presented by the Passions in their independent influences, and which become greatly complicated by their relations to foreign causes, by the variety of ways in which they are brought into operation, by the manner in which they modify the condition of organs so as to predispose them to the morbific action of foreign causes, or, again, defeat or promote the salutary effects of remedies, or as they are directly morbific or remedial themselves, and according to the nature and intensity of each, or by their production through mental sympathy, as in laughing, weeping, and even hiccough, or in that analogous but indefinable influence propagated from one to another, as witnessed in yawning, micturition, &c., but all of which are perfectly resolvable through the Author's doctrine of alterative and variously modified influence of direct and reflex action of the nervous system, evince their subjection to laws as peculiar as are all the phenomena (p. 112-121, § 234 c-237; p. 514, No. 7, parallel columns); and here the Author will extend the example which occurs at p. 866-867, § 1067, in relation to the influence of Fear upon digestion, and suppose that one of the individuals should reject the food from the stomach, in which case the emotion would simply render the nervous influence an irritant to the mucous tissue of the stomach, while the mechanical irritation of the food would develop, in conjunction with the gastric irritation by the passion, the reflex nervous action which determines the act of vomiting; and the analogy in substantive remote causes, and the sameness of the immediate exciting cause of the paroxysm become abundantly manifest in the fact that the mind itself may subsequently reproduce the act by calling

Mental Emotions-continued.

up a recollection of the event, and as described at p. 324, \$500 c; p. 547–548, \$63 d; p. 666, \$902 c, and under the Article Disgust. their influences, and the effects of the Will, employed by the Author in demonstrating the substantive existence and self-acting nature of the Soul and Instinctive Principle, p. 876-881, § 1071-1075. Also, Will, Index I.

and II.

how regarded in their relations to the higher powers of the mind, p. 877-

881, § 1072 b-1075.

from all which it appears that every consideration relative to the Mental Emotions -- their very nature, the variety of their effects in organic life, physiological, pathological, and therapeutical, the rapidity with which they may institute the changes, the manner in which they modify the operation of physical agents, the anatomical medium through which they exert their effects, denote the total absence of any connexion with the laws which govern the conditions of dead matter, while the complete analogies of their effects with those of physical causes, and the multitudinous variety of means which will arrest some given conditions of disease, and often with great instantaneousness, and in common with mental emotions, show that the physical causes, by this correspondence with mental emotions, are equally independent of chemical and physical laws; and their united force bears an overwhelming testimony in corroboration of what is so abundantly substantiated by the phenomena of the mental causes; nor is there a principle or a fact promulgated by Chemistry of practical application at the bedside of practical application at the beside of the sick, p. 296, § 476 c; p. 302, § 481 b; p. 377–380, § 578; p. 547–548, § 863 d; p. 664, § 900; p. 666, § 902 c; p. 667–669, § 902 e-g; p. 679–681, § 905 a; p. 707, § 947; p. 709, § 951 b; p. 866–868, § 1067; p. 889–890, § 1077. limited in a group to such as relieve pain and induce sleep, p. 583, § 891 a, b.

greatly overrated, p. 584, § 891 c; p. 715 -720, § 960 a; Note H p. 1117.

considerations relative to their injurious tendencies, and the neglect of more important means, ibid.

very deficient in curative virtues, and illustrations, p. 584, ◊ 891 d.

their modus operandi like that of all other remedies and of all morbific causes-that is to say, when their effects extend beyond their direct seat of operation, it is through alterative influences of reflex action of the nervous system-supplying examples, also, of the remarkable manner in which the nervous influence is variously modified and rendered alterative according to the nature of the causes by which it is brought into action, p. 107-111, 5, 6; p. 321–341, \(\delta\) 484 \(b\), Nos. 5, 6; p. 321–341, \(\delta\) 496–514 \(m; \) p. 567, \(\delta\) 889 \(k; \) p. 585, \(\delta\) 891 \(e; \) p. 589–590, \(\delta\) 891 \(e; \) p. 589–593, \(\delta\) 891 \(e; \) p. 665–675, \(\delta\) 902–904; p. 679–681, \(\delta\) 905 a. Also, Antispasmodics, Index II.

an example derived from Aconite applied to the skin in its sudden relief of neuralgia of the sciatic nerve, to show its operation through alterative influence of reflex nervous action, p. 838, § 10571.

analogy between the sedative effect exerted upon the nervous influence by Narcotics when developed by reflex action, and as developed in a direct manner by certain Emotions of the Mind, p. 296, § 476 c; p. 302, § 481

Narcotics-continued.

b; p. 589-590, § 891 p; p. 592-593, § 891½ k; p. 670, § 902 l. Also, Hiccough, Hysteria, Antispasmodics, Mental Emotions, Opium, Food, Index II.; Nervous Power, Index I. and II.

the variety in their virtues, respectively, of much practical advantage, p. 585,

6 891 f

their effects generally increase, at first, by frequent repetition, but subsequently decrease, though may be a good deal maintained by substituting one for another during their continued

use, ibid., and § 981 s.

directly sedative, as shown by their lessening morbid sensibility and irritability, and by the manner in which they counteract spasmodic affections, p. 590, \lozenge 891 q; p. 592–593, \lozenge 891 $\frac{1}{2}$ k; p. 828–833, \lozenge 1057 a–i

their greatest use, to produce sleep and relieve restlessness, though in this they may fail, or aggravate the trouble, when other means would be efficient, p. 586, § 891 g, h; p. 715-721,

§ 960 a, b.

their next great use, to relieve morbid states of *irritability*, through which opium arrests diarrhea, &c., with practical illustrations, p. 572, § 890 a; p. 576, § 890 l; p. 587, § 891 i.

next in order comes pain, for which they are mostly esteemed, and most abused—the symptoms commonly demanding very different remedies, such as loss of blood, blisters, warm bath and fomentations, p. 587-589, § 891 k-p; p. 715-

721, § 960 a, b.

their effects often counteracted by a peculiar stimulating nervous influence developed by pain, so that quantities are often admissible that would be fatal in health, p. 590, § 891 r—and again by a very different modification, as in the delirium of drunkenness, p. 590, § 891 r; p. 734, § 976 b.

the less important the part, the safer will they be, in a general sense, or where disease is not profound, p. 587-589,

§ 891 k-p.

less morbific in chronic than acute diseases, where, also, they are most successful, *ibid*.

NAUSEANTS,

a subdivision of Author's group of Seda-

tives, p. 830, § 1057 d.

prolific in examples of the operation of remedial and morbific agents through alterative influence of reflex action of the nervous system, of which Croup supplies one of the most obvious, where no amount of Tartarized Antimony or Ipecacuanha will moderate Nauseants-continued.

the symptoms till nausea takes place, when immediately a melioration often sets in, and advances rapidly when vomiting ensues-and, as the latter is admitted to depend upon reflex action of the nervous system, it goes with the former fact in showing that the disease is equally overcome by the same influence determined upon the mucous tissue of the larynx—while, also, the mineral and vegetable substance, in alike subduing the disease, demonstrates, like a thousand other analogous cases, the absurdity of the chemical and every other physical rationale, 551-554; p. 486, \$\delta 750 \ b; p. 532-533, \$\delta 841; p. 666-670, \$\delta 902 \ b-m; p. 675-676, \$\delta 904 \ b. Also, Antimony, Tartarized; Alteratives, Disgust, MENTAL EMOTIONS, Index II.

NEGRO.

his color, and that of other races, considered, p. 393, § 610; p. 907, § 1078 s. Also, Races of Mankind, Index I.; Medical and Physiological Comment-

aries, vol. ii., p. 640.

Nervous Power—continued from Ind. I. its existence, attributes, and functions, (whateverit may be, or if a better name can be substituted), as well as of the Organic Properties, more demonstrable than any thing relative to mere physics, p. 76, § 167 a; p. 79-81, § 167 g-169 f; p. 84, § 175 b; p. 85-87, § 175 d-177; p. 88, § 184 b, 185; p. 95-96, § 189 b; p. 111-121, § 234-237; p. 326-331, § 500 g-o.

although its existence as an agent is variously demonstrable, as above, it is sufficiently so by considering that all motions have a positive exciting cause-the lining membrane of the heart and bloodvessels is stimulated by the blood, the retina by light, the mucous tissue of the alimentary canal by food and bile, &c .- therefore the analogies prove that the muscles of respiration, the iris, the sphincter muscles, and all other muscles, must have an analogous cause, and when the variety in the results is considered, as arising from mental as well as physical causes, the great fallacy of the chemical rationale becomes glaringly apparent—and so of the Soul and Instinctive Principle, p. 62, § 136. Also, p. 107-122, § 226-240, and foregoing references, and Soul and In-STINCTIVE PRINCIPLE, Index II

nevertheless, the Author expresses himself as entirely opposed to all speculations as to the nature of such a power, and it is wholly unimportant whether

it be conceded that some other unknown influence (always excepting the chemical rationale) is exerted at the extremities of the excito-motory nerves, since, whatever it may be, it will in no respect affect the Author's application of the physiological laws of the nervous system in resolving the great problems in Pathology and Therapeutics, p. 117-118, § 234 g; p. 330, § 500 nn; p. 878-879, § 1073 a -but, in accepting this part of the alternative, it must be made to explain in some intelligible manner the endless variety of effects that ensue upon the operation of natural, morbific, and remedial agents, physical and mental (many of which are incapable of being absorbed), according to the nature of each one, and shown to be of some practical use in medicine, but which is perfectly resolved by the Author's doctrine of special modification of the nervous power by the several causes respectively. The term power is sanctioned by long usage and by late eminent writers, as Liebig, for example, when speaking of the functions of the nervous system (p. 158-171, Nos. 51-62, 65, 69, 70, 72-74, 79, 81, 87-91, parallel columns); but the present writer prefers the term nervous in-fluence (as he says of continuous sympathy, p. 322, § 498 a), which expresses his meaning exactly, and is exempt from all hypotheses, p. 88, § 184 b; p. 107–110, \(227–232 ; p. 112, \(\) 234 b; p. 302, \(\) 481 b; p. 305, \(\) 482 ; p. 309–314, \(\) 484–489 ; p. 323– 32, \(500 ; p. 333, \(5503 ; p. 334, \(\) 509 ; p. 405–412, \(\) 638 ; p. 530, \(\) 837 \(b ; p. 547–550, \(\) 863 \(d ; p. 661– 663, § 894 b-896; p. 665-670, § 902 a-m; p. 706-709, § 947-951.

operates upon the minute structure of organs, whether vascular, muscular, &c., and both by reflex and direct action, as it may be excited in one case through sensitive nerves, or in the other by causes acting directly upon the nervous centres, and through which action upon their organic states all the secreted products, and all the other natural conditions, are increased or diminished, or turned from their natural conditions, or again restored, in all parts beyond the seat of the direct operation of all causes which disturb its natural action-all organs being rendered preternaturally susceptible of the influences of the nervous system by their morbid state; and where it is not directly affirmed that all the foregoing results are due to

Nervous Power-continued.

influences of reflex or direct action of the nervous system upon the organic states, it is so by an obvious implication, for brevity's sake, founded upon the Author's universal application of the foregoing principle-and, farther, the nervous influence may prove a simple excitant or depressant, or, what is far more important, and distinctly and variously shown by unequivocal demonstration, and which can be expounded by no other philosophy, and which is fundamental in the Author's, it may, according to the nature of the causes, physical and mental, that bring it into preternatural action, undergo as great a variety of modifications as there are special virtues in the several causes, remedial or morbific, rendering it variously alterative, and from which results through the influences exerted by this protean agent upon the instruments of action the endless variety of changes that occur in the solids and fluids remote from the direct seat of operation in the case of all physical agents, and always so in the case of the Passions or other causes affecting the nervous centres, and even in the case of the direct seat of action the changes in the direct seat are apt to be consequent upon reflex actions coming either through the appropriate nerves of the part, or depend upon reflex actions excited by remote organs, p. 61, § 133 c; p. 63, § 137 d; p. 65, p. 61, § 133 c; p. 03, § 137 a; p. 03, § 143 c; p. 66-67, § 148; p. 101-102, § 201-203; p. 106-118, § 222-234; p. 125, § 245; p. 215, § 395; p. 226-227, § 410-411; p. 230-233, § 422-427; p. 250, § 446 c; p. 262, § 446 a; p. 264-270, § 446 d-447 d; p. 286, § 456 a, b, p. 301-302, § 481; p. 305-456 a, b; p. 301–302, \$\delta\ 481; p. 305–310, \$\delta\ 485-485; p. 323–336, \$\delta\ 995–512; p. 337, 338, \$\delta\ 514 c, d; p. 339–340, \$\delta\ 514 h; p. 344–345, \$\delta\ 516 d, \$\delt \Diamond 516 d, No. 13 ; p. 351, \Diamond 524 a ; p. 356–358, \Diamond 526 d ; p. 359, \Diamond 527 a,b ; p. 421–423, \Diamond 657–658 ; p. 451– 452, § 692; p. 486, § 750 b; p. 483- $-613, § 892\frac{1}{2} a, b; p. 631-632, § 892\frac{3}{4};$ p. 637, § 892\frac{4}{5} d, e; p. 642-648, § 893 a-g; p. 661-663, § 894-896; p. 666-672, § 902 b−904 a; p. 679−681, § 905 a; p. 692–695, § 915–924; p. 697– 701, \lozenge 927–928; p. 703–710, \lozenge 940–952; p. 831–833, \lozenge 1057 f–k; p. 862–864, \lozenge 1066; p. 865–868, \lozenge 1067; p. 875–877, \lozenge 1072 a; p. 886–891, \lozenge

1077. Also, REFLEX ACTION, MENTAL EMOTIONS, REMEDIAL ACTION.

exalts the condition of all organic compounds, solid and fluid, including the blood; a law profoundly concerned in pathology and therapeutics, \emptyset 226, 232, 399, 405, 446 a, 461, 485, 488 $\frac{1}{2}$, 512, 733 h, 746 c, 846, 902, 952.

explanatory specifications of the mechanism through which the nervous power operates in its function of reflex action, for the purpose of applying it to the interpretation of the modus operandi of all remedial and morbific agents upon parts beyond the seat of their direct operation, and also of its limitation in other cases to the motor nerves, and as the cause of all the physiological changes in the solids, and of all increased or otherwise modified secretions in parts not the immediate subjects of other agents through its various influences upon the instruments of organic processes, and of its modifications according to the nature of its exciting causes, as well, also, for proving the substantive existence and selfacting nature of the Soul and Principle acting nature of the South and 1 interpreted for Instinct, p. 101–102, § 201–202; p. 106, § 224–227; p. 112, § 234 b; p. 116–117, § 234 f; p. 282, § 451 d; p. 285–287, § 455 d–459 a; p. 290–295, § 462–475½; p. 300, § 479; p. 309–310, § 484 b, Nos. 5 and 6; p. 281, § 406, 407; p. 323, 328, § 4496 321, § 496, 497; p. 323–328, § 499 a -500 m; p. 331–341, § 500 o-514 n; p. 344–345, § 516 d, No. 6; p. 348, § 516 d, No. 13; p. 416–417, § 649 c; p. 421–423, \(\) 657–658; p. 465–466, \(\) 715; p. 483–484, \(\) 746 \(c \); p. 592–593, \(\) 891\(\) \(k \); p. 661–663, \(\) 894– 896; p. 665–670, \(\phi \) 902 a-n; p. 679–681, \(\phi \) 905 a; p. 703–710, \(\phi \) 940–952; p. 873–881, \(\phi \) 1069–1075; p. 886–891, \(\phi \) 1077; \(\phi \) 111–113, 224, 488\(\frac{1}{2} \), 524 d, no. 7, 891\(\frac{1}{2} \) g, 893 a.

nevertheless, the Author endeavors to show that the functions of organs in the organic life of Animals are carried on, like the analogous ones in Plants, by properties inherent in all parts, and that the nervous power or nervous influence contributes nothing more toward the functions of the nutritive and other secretory vessels than that of exerting a modifying, or exciting, or depressing influence upon them, through which the products are perfected in their character, or increased or diminished; but these instruments of life are constantly liable to preternatural influences of the nervous power, and of an endless variety, and there is no function in the natural

Nervous Power-continued.

state of the body, no condition of disease, no action of remedies, in which the nervous influence does not participate (p. 54-55, § 109 b-117; 284-287, § 454 c-459; p. 289, § 461; p. 483-484, § 746 c), while organs in their compounded condition are more manifestly under its perpetual harmonizing influence through the impressions made upon their minute structure - it being, therefore, the Author's doctrine that the nervous influence is merely an exciting or modifying cause of the organic functions, and whenever he speaks of that influence as a cause of certain effects, or objects to its application as a cause of any of the processes of life, he always means in the former case that it influences the processes of life, and in the latter that these processes are carried on by causes or properties inherent in all parts, p. 23, § 34–38; inherent in all parts, p. 23, $\sqrt{34-38}$; p. 24, $\sqrt{44}$, 42; p. 54, $\sqrt{5}$ 109 b; p. 66–67, $\sqrt{5}$ 148; p. 75–76, $\sqrt{5}$ 167 a; p. 110, $\sqrt{5}$ 233; p. 222–227, $\sqrt{5}$ 409 c–411; p. 284–286, $\sqrt{5}$ 454–457; p. 289, $\sqrt{5}$ 460–461½; p. 294, $\sqrt{5}$ 475; p. 295, $\sqrt{5}$ 460–476 b; p. 313–315, $\sqrt{5}$ 488–489; p. 317–318, $\sqrt{5}$ 493; p. 421–423, $\sqrt{5}$ 657–658; p. 483–484, $\sqrt{5}$ 746c; p. 353, no. 7. VITAL PROPERTIES, ORGANIC LIFE, Index I.; Respiration, Sphineter Muscles, &c., Index II. § 990½ a, b.

is the agent through which the Will and Mental Emotions operate. See Will, Index I and II.; Mental Emotions, and the individual Passions, Index II.;

NERVOUS POWER, Index I.

but there is an essential difference in the influence of the nervous power upon organs that are less interested, or not at all, in the essential processes of organic life, where, as in voluntary motion, respiration, contraction of the sphineter muscles, peristaltic movements, the nervous power is the only immediate stimulus which brings the muscles into action; though here, also, the motions are accomplished by inherent powers, p. 110, § 233, and many of the preceding references. Also, VITAL PROPERTIES, NERVOUS POWER, Index I; SPHINCTER MUSCLES, RESPIRATION, IRIS, CATHARTICS, Index II.

its development direct when the Will or Mental Emotions operate, or any disturbances affect the nervous centres, and indirect when the exciting influences proceed from other parts through sensitive nerves or fibres, and the transmitted impression develops the nervous influence—consti-

tuting reflex action of the nervous system or remote sympathy-both orders of nerves or fibres of compound nerves being always engaged in the latter case, while in the former, when the Will and Passions operate, the excito-motory nerves or fibres are alone concerned, and the influence alone centrifugal, unless the Passions, as is common, and diseases of the nervous centres, &c., institute impressions upon distant parts that are reverberated upon the nervous centres, when the nervous influence, although direct at its incipient movement, may establish a complex circle of reflex actions, and undergo modifications of its alterative influence, not only according to the nature of its primary exciting cause, but according, also, to that of the particular natural constitution of different parts, and any present modified condition of parts upon which its influences may fall, since, also, any preternatural condition of an organ, whether rendered temporarily so by disease, or only temporarily disturbed by the nervous influence (as in sneezing from a strong light impinging upon the retina, p. 327, \S 500 i; p. 333, \S 504; p. 340–341, \S 514 l), is equivalent to influences propagated in a like manner by the action of remedial and morbific agents, and will modify the nervous influence in a corresponding manner; and upon this reflected influence and its modifications depend the diseases of organs that grow out of each other, and the nature of the affections as they may spring up consecutively, and in connexion with the constitutional nature of different parts, or as they may conspire together in aggravating or relieving the condiaggravating of renewing the conditions of each other, p. 59, \lozenge 129 h, i; p. 61–68, \lozenge 133–152; p. 73, \lozenge 163; p. 101–102, \lozenge 201–202; p. 107–119, \lozenge 224–234; p. 282–284, \lozenge 451–453; p. 285–286, \lozenge 455; p. 296, \lozenge 476 c; p. 321, \lozenge 496, 497; p. 323–328, \lozenge p. 347–348, \(\) 516 \(d \), No. 13, 517; p. 429–430, \(\) 674 \(d \); p. 526, \(\) 828 \(d \); p. 539, 0.848; p. 592, $0.891\frac{1}{2}$ k; p. 710, \lozenge 940–952; p. 745–746, \lozenge 990½; p. 831–833, \lozenge 1057 f–h; p. 838, \lozenge 1057½; p. 865–868, \lozenge 1067; p. 874–881, \lozenge 1071–1075; p. 886–891, \lozenge

Nervous Power—continued.

"exhaustion of," an hypothesis without foundation, p. 805, § 1041.

when remedies properly applied (as with morbific causes) develop the alterative action of the nervous influence, it is not commonly by exciting disease in parts which are the direct seat of their operation, but when this result ensues it is mostly through reflex action of the nervous system directed upon the seat of their operation—though prominent exceptions occur in the case of Counter-Irritants, p. 66-67, § 148; p. 336, ϕ 514 b-h; p. 416–417, ϕ 649 c; p. 421–423, ϕ 657–658; p. 483–484, \$ 746 c; p. 522-523, \$ 827 b, c; p. 862-864, \$ 1066. Also, Miasm, Skin,

COLD, &c., Index II.

considered in its slowly progressive operation through reflex action of the nervous system, when brought into effect by agents belonging to Author's group of Alteratives, and analogous means, both physical and mental-the same being also true of the slowly progressive operation of morbific causes, p. 111, \Diamond 233½, 233½; p. 285–286, \Diamond 455 d–f; p. 333, \Diamond 503– 5. 253-250, 453 dry; p. 363, 9503-506; p. 339, § 514 g; p. 344-345, § 516 d, No. 6; p. 365, § 551; p. 366, § 556; p. 416-417, § 649 c; p. 420-424, § 654-661; p. 532, § 841; p. 547, § 863 d; p. 551, § 877; p. 568-569, § 889 m, mm; p. 646–649, § 893 e-h; p. 661–663, § 894–896; p. 668– 670, § 902 g-m; p. 675-676, § 904 b; p. 679-681, § 905 a. Also, SPHINCTER MUSCLES, ALTERATIVES; HYDROPHO-BIA, VIRUS OF; SMALL-POX, MIASM, PREDISPOSITION, Index II.

may operate profoundly with morbific, but little with remedial effect, long after the exciting cause is withdrawn, ♦ 545; p. 365, ♦ 549, 550; p. 368, ♦ 558, 560; p. 416–417, \(\) 649 c; p. 420–424, \(\) 654–661; p. 425–427, \(\) 664–666; p. 532, \(\) 841; p. 542, \(\) 854 c-e; p. 668–669, \(\) 902 g; p. 707

−708, § 949. the incorporation of the cerebro-spinal and ganglionic systems in all parts renders them all the constant subjects of direct and reflex nervous influence; but in the natural state of the body this influence is not strongly pronounced, excepting in certain instances, as respiration, the contrac-tion of the sphincter muscles, the motions of the iris, of the stomach and intestine, and of the heart; but

otherwise mostly so when morbific and remedial agents and the mental emotions operate, p. 55, \lozenge 111-117; p. 58-59, \lozenge 129 a, i; p. 61, \lozenge 133 c; p. 62-67, \lozenge 136-151; p. 87, \lozenge 177; p. 88, \lozenge 184-185; p. 101-102, \lozenge 201-202; p. 106-112, \lozenge 222-234; p. 116-117, \lozenge 234 f, g; p. 253, \lozenge 441 d; p. 262-268, \lozenge 446 a-447 d; p. 284-290, \lozenge 454-461½ c; p. 296, \lozenge 476 c; p. 323-341, \lozenge 499-514; p. 344-345, \lozenge 516 d, No. 6; p. 348, \lozenge 516 d, No. 13; p. 350-353, \lozenge 5524; p. 354-362, \lozenge 526-530; p. 508-509, \lozenge 807-811; p. 537-539, \lozenge 847 e-848; p. 563-565, \lozenge 889 a-g; p. 592-593, \lozenge 891½ k; p. 642-650, \lozenge 893 a-i; p. 657, \lozenge 893 p; p. 661-681, \lozenge 894-905; p. 692-709, \lozenge 914-951; p. 745-747, \lozenge 990½ a, b; p. 804, \lozenge 1040; p. 865-868, \lozenge 1067; p. 874, \lozenge 1071; p. 877-881, \lozenge 1072 b-1075; p. 886-890, \lozenge 1077, 891½ g.

other strongly marked examples of reflex action of the nervous system, and of an alterative nature, occur in natural mutations of the body from Infancy to Youth, and others in other natural conditions to which the system is incidentally liable, as in gestation and lactation. See Youth, Lactation, Uterus, Organs of Generation,

MILK, Index II.

the entire dependence of respiration upon reflex action of the nervous influence coincides with the dependence of the act of vomiting upon the same causation, and carried by the Author through a chain of analogies consisting of the various modifications of respiration, of vomiting as produced by emetics of various kinds, by loss of blood, by tickling the fauces, by tobacco applied to the soles of the feet, by pregnancy, by shock of falls, by mental emotions, &c., and the divers influences and results according to the nature of the cause, and other coincidences supplied by the iris, sphincter muscles, skin, cold, suppositories, tetanus, &c., which depend upon other modifications of the nervous influence through reflex action, and the analogies supplied by the will in voluntary motion—all carried to the interpretation of all the effects of active emetics and cathartics, both remedial and morbific, and by the same analogies, their effects, when they fall short of vomiting or purging, or other prominent results that arise from larger doses, through alterative influences of reflex action of the nervous system, upon parts beyond the seat of their direct operation, and

Nervous Power-continued.

against the chemical and physical doctrines of operation through absorption-and all this chain of analogies applied to the modus operandi of all other remedial and morbific causes, physical and mental, while the same interpretation of all the others is sustained by other special demonstrations in immediate connexion with a large number of the several things respectively, p. 66-67, § 148; 5; P. 601-003, γ 638-333, γ 600-672, γ 902 b-904 b; p. 679-681, γ 905 a; p. 703-710, γ 940-952; p. 831-833, γ 1057 f-g; p. 838, γ 1057½. Also, STOMACH, NAUSEANTS, SKIN, COLD, SHOWER BATH, TETANUS, DISGUST, SYNCOPE, and the several Articles under GENERALIZATION OF REFLEX ACTION OF THE NERVOUS System, Index II.

examples of its effects in subduing violent inflammations, augmenting and altering the natural secretions, and of variously and suddenly modifying the condition of morbid fluid products, and the condition of the blood, when brought into operation by Mental Emotions, p. 296, § 476 c; p. 230-232, § 422 b-424; p. 335-336, § 512 a, b; p. 630-632, § 892\frac{3}{2} b; p. 709-710, § 951 b-952; p. 865-868, § 1067; p. 877-878, § 1072 b. Also, MILK, SWEAT, URINE, FOOD, WEEPING, MENTAL EMOTIONS, Index II.; SU-

DORIFICS, Index I.

is the exciting cause of all diseases which spring up as consequences of each other; but the secondary affections, one or more, may be very different from the primary, depending, in part, upon the peculiar constitution of different tissues, or parts of a tissue, p. 62-68, § 135-152; p. 109, § 229; p. 339-340, § 514 h; p. 465-469, § 715-722; p. 483-484, § 746 c. Also, Causes, Morbiffic; Inplanmation, Skin, Tobacco, Seton, Index II.

expounds the philosophy of Metastasis and Revulsion. See METASTASIS.

Index II.

may operate upon the organic constitution of the nervous centres, and thence upon the heart, stomach, &c., with a suddenly fatal effect, through reflex action of the nervous system, as with

blows upon the epigastrium, surgical operations, hydrocyanic acid, &c., or directly through its sudden and violent determination upon the brain, as in the case of joy and anger, when it may act by suddenly destroying the life of the brain, and also farther exemplified by the sudden determination of syncope, and the consequent sudden interruption of pleurisy, &c., through direct and reflex action of the nervous system, and equally acts upon all other parts of the nervous system, p. 107-111, \lozenge 226–233 $\frac{3}{4}$; p. 296, \lozenge 476 c; p. 298, \lozenge 476 $\frac{1}{2}$ h; p. 300, \lozenge 479; p. 301, \lozenge 480; p. 302, \lozenge 481 b; p. 304, \lozenge 481 9 480; p. 302, $\sqrt{461}$ b; p. 302, $\sqrt{461}$ g; p. 306, 308, $\sqrt{483}$ b; p. 320, $\sqrt{9494}$ dd; p. 324, $\sqrt{500}$ c, d; p. 334–335, $\sqrt{509-511}$; p. 402–403, $\sqrt{634-635}$; p. 534, $\sqrt{844}$; p. 704, $\sqrt{943}$ a–944 a; p. 707, $\sqrt{947}$; p. 709, $\sqrt{951}$ b–d; p. 831–833, $\sqrt{1057}$ f–g; p. 858, $\sqrt{1057}$ ½; $\sqrt{943}$ d. $\sqrt{1066}$ p. $\sqrt{865-868}$. p. 862-864, § 1066; p. 865-868, § 1067; p. 878-881, § 1074-1075; p. 887, § 1077. PURPURA HEMORRHAGICA,

its pathology, and treatment by bloodletting, p. 754, § 1002 d-f.

Pus.

a new formation, the result of a secretory process brought about by inflammation, and which constitutes a natural termination of the formative stage of that disease, p. 471, § 730.

liable to be affected in its condition by causes acting locally, but more generally through alterative influences of reflex action of the nervous system originating in some internal disease, or by the same influences propagated in a direct manner upon the instruments of its formation by Mental Emotions, p. 478-480, § 740-741. Also, Inflammation, Secretion and Excretion, Milk, Bille, Reflex Action, Mental Emotions, Sympathy, Index II.; Nervous Power, Index I. and II.; VITAL PROPERTIES, Suddingters, Index I.

allied, in principle, to lymph, mucus, and serum, when the latter are products of inflammation—each being consequences of the formative stage, p. 471–472, § 732 b-733, and references there; p. 474–475, § 733 f-h—all of which are designed for useful ends, but lymph and pus most so, p. 471–476, § 732–733; p. 546–547, § 862–863; p. 550–551, § 863 e-864.

all its varieties, like those of mucus, depend upon precise pathological conditions, and more or less upon the natural constitution of the part—which may be presented to Organic Chemistry as a problem for its solution, taking along the Mental Emotions as among the causes which modify the pathological states, p. 120–121, § 237; p. 452, § 693; p. 478–480, § 739–741 b. Also, p. 61–62, § 133–136; p. 67, § 149–151; p. 224, § 409 b; p. 226, § 410; p. 436, § 682 b, 409 d.

R.

RACE, HUMAN, UNITY OF—continued from Index I.,

briefly considered, p. 906-907, § 1078 s.

RECUPERATION, LAW OF,

so designated by the Author in preference to Vis Medicatrix Natura—ingrafted upon the constitution of all organic beings, and upon which the Art of Medicine reposes, and without which the whole animal kingdom would perish. See VIS MEDICATRIX NATURAE, VITAL PROPERTIES, ORGANIC LIFE; ADAPTATION, LAW OF, Index I.; REMEDIES; CAUSES, MORBIFIC; DISEASES, SELF-LIMITED, Index II.

instability of the properties of life, or-dained for useful purposes, and their inherent tendency to maintain themselves in their normal state, lie at the foundation of Therapeutics, and the former, especially, of disease-morbific causes altering them in one way, and remedies in another less pro-foundly morbid, by which the law of recuperation is brought into effect, and this mutability is the source of natural changes which the system undergoes either in function or development of structure, as manifested in gestation, lactation, &c., and in the transition stages from infancy to adult age, in metamorphosis, &c., and is displayed in its morbific aspect by the impregnated ovum, p. 44-49, § 67-80; p. 61, § 133 c; p. 68-69, § 152-156; 9. 83, \$\sqrt{174}; p. 87, \$\sqrt{177-182}; p. 88, \$\sqrt{184} b; p. 95-96, \$\sqrt{189} b; p. 98, \$\sqrt{191} a, b; p. 108, \$\sqrt{228} a; p. 109-110, \$\sqrt{230-232}; p. 120-122, \$\sqrt{237-240}; p. 131-132, \$\sqrt{285}; p. 352, \$\sqrt{254}\$ 557, 584, \$\cdot \cdot \ p. 664-665, § 899-901; p. 736, § 980; p. 902, § 1078 p; p. 435, § 680. UTERUS, ORGANS OF GENERATION, PARTURITION, Index II.; VITAL PROP-ERTIES, VIS MEDICATRIX NATURÆ; ADAPTATION, LAW OF, Index I.; YOUTH, Index I. and II.

REFLEX ACTION OF THE NERVOUS SYSTEM AND DIRECT ACTION,

the term direct, and its distinction from reflex (the latter of which the Author sometimes designates as indirect, and oftener Sympathy), introduced as the basis of his interpretation of the modus operandi of the Will and Mental Emotions, and of the nervous influence as excited by affections of the nervous centres, and for expounding, along with reflex action, the modus operandi of Loss of Blood, and for demonstrating the substantive existence and self-acting nature of the Soul and Instinctive Principle—and, as farther explain-

ed, the Author means by the term direct that the excito-motory nerves or fibres of compound nerves are alone engaged, unless the Passions, as is common, and diseases of the nervous centres, &c., institute impressions upon distant parts that are reverberated through centripetal nerves upon those centres, when the nervous influence may thus establish complex circles of reflex actions, and undergo modifications of its alterative influence according to the nature of the mental emotion or any affection of the nervous centres, as, also, according to that of the particular natural constitution of different parts, and any present modified condition of parts upon which it may fall, since, also, any preternatural condition of an organ, whether rendered temporarily so by disease, or only disturbed by the nervous influence (as in sneezing from a strong light impinging upon the retina, p. 327, § 500 i; p. 333, \$504; p. 340-341, \$514 l), is equivalent to influences propagated in like manner by the action of remedial and morbific agents, and will modify the nervous influence in a corresponding manner; and upon this reflected influence and its modifications depend the diseases of organs that grow out of each other, and the nature of the affections as they may spring up consecutively, and in connexion with the constitutional nature of different parts, or as they may conspire together in aggravating or relieving the conditions of each other -subject always to variations from age, sex, habits, &c., and although the nervous influence as propagated upon the voluntary muscles always terminates in the simple production of voluntary motion so long as the Will continues to operate, there is the remarkable exception of roosting, and some examples of man sleeping in an erect posture, in which it establishes an unceasing reflex action, and occasional instances of vomiting in which the Will is a concurring cause with some mechanical irritation of the stomach, p. 59, § 129 h, i; p. 61-68, \$\cdot 133-152; p. 73, \$\cdot 163; p. 101-102, \$\cdot 201-202; p. 107-119, \$\cdot 227-234; p. 282-284, \$\cdot 451-453; p. 285-286, \$\cdot 458. d, No. 13, 517; p. 429-430, § 674 d; p. 526, \$828 d; p. 539, \$848; p. 592, \$891\frac{1}{2} k; p. 646-648, \$893 e-g; p. 661-663, § 894-896; p. 665-676, §

Reflex Action, &c .- continued.

902 a-904 b; p. 679-681, \$ 905 a; p. 692, \$ 914-921; p. 698-699, \$ 930-935; p. 703-710, \$ 940-952; p. 745-746, \$ 990½; p. 831-833, \$ 1057 f-h; p. 838, \$ 1057½; p. 865-868, \$ 1067; p. 874-881, \$ 1071-1075; p. 886-891, \$ 1077. Also, WILL, NERVOUS POWER, SYMPATHY, Index I. and II.; MENTAL EMOTIONS; BRAIN, INFLAMMATION OF; ROOSTING, Index II.

rejecting entirely the exceedingly simple doctrine of Chemistry as to the agency of the nervous system in the various processes and products of the animal kingdom, and which have no reference to the physiological laws of that system, but consisting alone in an abstract idea, the Author maintains in all his principal writings, as the groundwork of their philosophy, that the nervous system is endowed with a property, power, or influence (no matter which) that operates as a vital agent, and is so far on common ground with other vital agents, and that it is susceptible of an endless variety of modifications according to the nature of the causes by which it is brought into action, and that there is imparted to it the essential virtues of the various causes respectively, both physical and mental, and that when morbific and remedial agents bring about changes in the natural condition of the solids and fluids, in parts beyond the seat of their direct action, or whenever analogous effects are exerted by the Mental Emotions, or when diseases ensue upon each other, or when one disease becomes the cause of relief to another, whether natural or artificial, it is always by alterative influences of direct or reflex action of the nervous system determined upon the capillary vessels, or main instruments of all organic functions, and that these influences depend not only on the nature of the exciting causes and other accidental circumstances, but also more or less upon the special vital constitution of different tissues and different parts of a continuous tissue-and whether, therefore, the Chemical Philosopher have any vague regard to the nervous system, or ascribe, as he mostly does, all the results of physical agents to their absorption and direct chemical action, and leaves the "action of the nerves" and mental phenomena obscured by "a veil which is not to be raised" (p. 183, § 350\frac{3}{3} gg), the difference between him and the Author consists in the violation by the former of all the facts and analogies supplied

by that inorganic world from which he professes to derive his conclusions, and the absolute inapplicability of any one of the doctrines to practical medicine, while the Author presents, as he believes, a perfectly consistent array of an endless series of facts and of practical doctrines which are incontrovertible in every detail, and which has the special merit of bringing the Author's doctrine of the operation of the Mental Emotions and the Will through the medium of the nervous influence into perfect harmony with that of all physical causes, p. 59, \$ 127 i; p. 65, \$\delta\$ 143 b, c; p. 67-68, \$\delta\$ 149-152; p. 89, \$\delta\$ 188; p. 101-102, \$\delta\$ 201-202; p. 106-111, \$\delta\$ 222-233\delta\$; p. 230-233, \$\delta\$ 242-427; p. 282-284, \$\delta\$ 153, p. 255, \$\delta\$ 5.455 b. 451 + 453; p. 285, \(\) 455 \(\) 5, \(f \); p. 295 \(\) -296, \(\) 476 \(\) b, \(c \); p. 301-304, \(\) 480-481; p. 305, \(\) 481 \(\) b; p. 307-308, \(\) 483 \(c \); p. 310, \(\) 484, \(\) Nos. 5, \(6 \); p. 310, \(\) 484, \(\) 485, \(\) 281, \(\) 485, \(313, \(\) 487 \(h \); p. 314, \(\) 488\(\); p. 321, \(\) 496, 497 ; p. 323-328, \(\) 499 \(b - 500 \)

Reflex Action, &c .- continued.

these exact coincidences between the natural, remedial, and morbific agents an irresistible proof that the latter exert their effects equally with the former through the medium of reflex action of the nervous system (or originally direct in the case of Mental Emotions), and which renders the chemical, galvanic, electrical, and other physical hypotheses simply ridiculous, p. 75–79, \Diamond 166–167 f; p. 112, \Diamond 234 a; p. 111, \Diamond 233 $\frac{3}{4}$; p. 116, \Diamond 234 f; p. 326–328, \Diamond 500 g-m; p. 330, \Diamond 500 m; p. 666–672, \Diamond 902 b–904 b. Also, p. 174–183, \Diamond 350 $\frac{1}{2}$ –350 $\frac{3}{4}$ gg.

various explanations relative to the mechanism through which the nervous influence operates in its function of reflex action, for the purpose of applying it to the interpretation of the modus operandi of all remedial and morbific agents upon parts beyond the seat of their direct operation, and also of its limitation in other cases to the motor nerves, or as direct impressions when thus produced may give rise to reflex actions, and as the cause of all the physiological changes in the solids and of all increased or otherwise modified changes in the fluids, through its various influences upon the instruments of organic processes, and of its modifications according to the nature of its exciting causes, as well, also, for proving the substantive existence and self-acting nature of the Soul and Principle of Instinct, p. 101–102, § 201 –202; p. 108, § 227, No. 2; p. 112, § 234 b; p. 116–117, § 234 f; p. 282, § 451 d; p. 285–287, § 455 d–459 a; p. 290-296, $6462-476\frac{1}{2}$; p. 300, 6479; p. 309-310, 484 b, Nos. 5 and 6; p. 312-315, § 487 g-489; p. 321, \$ 496, 497; p. 323-328, \$ 499 a-500 \lozenge 496, 497; p. 323–328, \lozenge 499 a–500 m; p. 331–341, \lozenge 500 a–514 n; p. 344–345, \lozenge 516 d, No. 6; p. 347–349, \lozenge 516 d, No. 13–520; p. 416–417, \lozenge 649 c; 421–423, 657–658; p. 465–466, \lozenge 715; p. 484, \lozenge 746 c; p. 523, \lozenge 827 c; p. 565–566, \lozenge 889 f, g; p. 592–593, \lozenge 891 1_2 g, k; p. 642–647, \lozenge 893 a–e; p. 661–663, \lozenge 894–896; p. 665–670, \lozenge 902 a–n; p. 679–681, \lozenge 905 a; p. 703–710, \lozenge 940–952; p. 733–734, \lozenge 974 c–975 b; p. 873–881, \lozenge 1069–1075: p. 886–891, \lozenge 1077. 1075; p. 886-891, § 1077. A Nervous Power, Index I. and II. Also,

its essential principle, the nervous power, or whatever it be, is not a movable substance, in transitu from part to part, but, like the principle of Light, is every where diffused through its appropriate medium, and, like that principle, is brought into operation by

exciting causes, and with every variety of effect, according to the nature of the causes; nor is there any greater difficulty in understanding its imputed modifications than the polarization of light, or any other attributes which the Author assigns to them, than such as appertain to Light, p. $80, \, 6169 \, b, \, d$; p. $84, \, 6175 \, b, \, bb$; p. $80, \, 6184 \, b$; p. $110, \, 6232$; p. $114-120, \, 6234 \, e-235$; p. $330, \, 6500 \, nn$; p. $334, \, 6507$; p. $670, \, 6902 \, k$.

its application to the modus operandi of all remedial and morbific causes is founded upon natural laws; and the Author maintains that, if there be any thing in the consistency of Nature, or any thing in facts, the same physiological laws which govern the organization of the animal kingdom in its normal state are equally at the foundation of all its deviations from the natural standard, and that this universal principle embraces completely the physiological laws of the nervous system, which, indeed, the Author has demonstrated by a multitude of exact coincidences between the results of natural causes and those of a morbific and remedial nature, both physical and mental, as appears in a summary manner in the following sections, and in great amplification under the topics embraced in the Article Generalization of Reflex Action, Index II., p. 1–2, \lozenge 1 a; p. 3–4, \lozenge 2 b–d; p. 106–112, \lozenge 222–234 b; p. 282–295, \lozenge 451–475; p. 321–362, \lozenge 495–530; p. 405– 412, § 638; p. 413, § 639-640; p. 541 -543, § 852 a-857; p. 661-678, § 894 -904; p. 679-681, § 905 a; p. 692-693, § 915–921; p. 698–699, § 929– 935; p. 703-711, ◊ 940-952. Also, AND INSTINCTIVE PRINCIPLE, Ind. II.— \Diamond 718, 795, 892 b, 990\(\frac{1}{2}\) a, b.

the entire dependence of respiration upon reflex action of the nervous system, as the stimulus of the muscular mechanism, coincides with the dependence of the act of vomiting upon the same causation, and carried by the Author through a long chain of analogies consisting of the various modifications of respiration, of vomiting as produced by emetics of various kinds, by loss of blood, by tickling the fauces, by tobacco applied to the soles of the feet, by pregnancy, by shock of falls, &c., and by Mental Emotions, and the divers influences and results according to the nature of the cause, and other coincidences supplied by the iris, sphincter muscles, heart, cold, suppositories, tetanus, &c., which deReflex Action, &c-continued.

pend upon other institutions of the nervous influence through centripetal and centrifugal nerves, and the analogies supplied by the Will in voluntary motion-all carried to the interpretation of all the effects of active emetics and cathartics, both remedial and morbific, and, by the same analogies, their effects when they fall short of vomiting and purging, or other prominent results that arise from larger doses, through alterative influence of reflex action of the nervous system, and against the chemical and physical doctrines of operation through absorption—and all this chain of analogies applied to the modus operandi of all other remedial and morbific causes, physical and mental, while the same interpretation of all the others is sustained by other special demonstrations in immediate connection with a large number of the several things respectively, p. 66-67, ∮ 148; p. 110, ∮ 232; p. 323-341, ∮ 499-514 m; p. 334-335, § 516 d, No. 6; p. 347-348, § 516 d, No. 13; p. 421-423, \lozenge 657-658; p. 526, \lozenge 828 a; p. 532-533, \lozenge 841; p. 542-543, \lozenge 854 c-f; p. 547-550, \lozenge 863 d; p. 563-566, \lozenge 889 a-g; p. 568-569, \lozenge 889 m, mm; p. 592-593, \lozenge 891½ k; p. 631-632, § 892\(\frac{1}{2}\) b; p. 661-663, 894–896; p. 666–678, \$ 902 b–904 d; 940-952; p. 831-833, \$ 1057 f-g; p. 838, \$ 1057\frac{1}{2}\$. applied in expounding the modus operandi of Cinchona, Loss of Blood, and of other things of which we are said to be ignorant, and in connexion with illustrations drawn from the modus operandi of a Seton, and where, also, under the several references, the organic influences of remedial agents through the instrumentality of nervous action, and the philosophy which concerns their substitution of transitory pathological conditions for the more profound as the fundamental cause of cure, is summarily presented, p. 596–597, § 892 b, c; p. 676–681, § 904 b–905 a. Also, p. 67, § 149-151; p. 73, § 163; p. 108-110, § 227-232; p. 542, § 854 c-e; p. 554, § 871; p. 592-593, § 891½ k; p. 661-663, § 894-896; p. 664-665, § 900-901 Also, BLOODLETTING, REME-DIES, &c., Index II.

Reflex Action, &c .- continued.

but it is not alone the foregoing analogies, as supplied by respiration, vomiting, &c., and a multitude of others of a corresponding nature, that are tributary to the Author's doctrine of the modus operandi of remedial and morbific agents, through reflex or direct action of the nervous system, but an almost universal proof to the same effect is supplied by all the muscular movements in organic life, by that of the muscular coat of the intestinal canal, by the muscles of deglutition, that of the bladder, that of the uterus, &c., and, what is especially important, by the heart and entire arterial and venous systems, whose active motions, if not wholly determined as it respects their exciting cause, are at least greatly influenced by the reflex action of the nervous system excited by the stimulus of blood, being wholly true of the heart, p. 301-310, § 481-485; p. 338-339, 514 f; p. 343, 344-348, § 516 d, Nos. 3-5, 7, 12, 13, and conspicuously so by mental emotions, food, exercise, &c., and by diseases generally, all of which is referable alone to the stimulus of nervous influence-upon which, collectively, is founded, in part, the Author's doctrine of the action of the capillary arteries and of the veins as among the important elements in the circulation of the blood, p. 62, § 136; p. 209-210, § 384-387; p. 211, § 390 b, and deduced, in farther part, from experiments made upon arteries by Buniva, Procter, and Kreimer, p. 215-216, § 399; p. 310, § 485, and subsequently confirmed by Brown-Séquard and others, p. 803-804, § 1039; p. 805, § 1041—and which is at the foundation. in part, of the Author's theory of the active condition of the instruments of inflammation, p. 485-486, § 750-751, and references there, and of his theory, also, of the ready transition of venous congestion into the ordinary form of inflammation, p. 506-507, § 803, 804—and in consideration of all of which, and of the manifest influences of the nervous system upon the capillary bloodvessels (those main instruments of all organic processes and their results, p. 226-227, § 410, 411) that are determined upon them by a vast variety of the natural stimuli of life, physical and mental, it cannot be doubted that all remedial and morbific agents must of necessity exert, through that same nervous influence, more powerful and disturbing effects upon those instruments, and thus become

the immediate exciting cause of disease, of the increase, diminution, and other changes in the secretions, and equally also of those pathological variations impressed by remedial agents, and through which the more profoundly morbid are placed in the way of the recuperative process, p. 541–542, § 852–854 e; p. 664–665, § 899–901. Also, Skin, Cold, Kidney, Organs of Generation, Uterus, Parturition, Food, Fear, Disgust, Nervous System, &cc., Index II.; Vital Properties, Organic Life, Index I.; Nervous Power, Index I. and II.

but the nervous influence is in no fundamental sense, as is generally supposed, the cause of the organic functions in Animals any more than of the analogous functions of Plants, which are carried on by properties implanted in all parts, but contributes a modifying and exciting or depressing influence to the nutritive and other secretory vessels, through which the products are perfected, or increased, or diminished; but these instruments are constantly liable to preternatural influences from either direct or reflex nervous action, and of an endless variety, and there is no function in the natural state of the body, no condition of disease, no action of remedies, in which the nervous system does not participate (p. 54-55, § 109 b-117; p. 284-287, § 454 c-459; p. 289, § 461; p. 483-484, § 746 c), while organs in their compounded condition are more evidently under its perpetually harmonizing influence through the impressions made upon their minute structure-and coming to many functions that are less concerned, or not at all, in the essential processes of organic life, as in respiration, contraction of the sphincter muscles, motion of the iris, peristaltic movements, &c., the nervous influence is the only immediate exciting cause - an obvious distinction, therefore, being made by the Author between the nervous influence as an exciting or modifying cause or vital agent and the fundamental causes or organic properties by which. in connexion with organization, the functions are carried on; and hence, whenever the Author speaks of the nervous influence as a cause, he simply means an exciting or modifying cause, p. 23, § 34–38; p. 24, § 41, 42; p. 54–55, § 109 b–117; p. 66–67, § 148; p. 75–76, § 167 a; p. 88, § 183, 184; p. 110, § 233; p. 222–227, § 409 c-411; p. 284–286, § 454–457; p.

recent observations upon, confirming important principles in these Institutes,

p. 803–808, § 1039–1045.

the coincidences in effects of reflex and direct action of the nervous system, or as the centripetal and centrifugal nerves are engaged in the former process, and the centrifugal alone in the latter, form the basis of the Author's demonstration of the substantive existence and self-acting nature of the Soul and Instinctive Principle, p. 873 –910, \$ 1069–1082. Also, MENTAL EMOTIONS, the individual Passions, Index II.; WILL, Index I. and II.

employed by the Author to expound the dependence of the first act of respiration, when the point of departure is from the skin, in Medical and Physiological Commentaries, and again in the original Essay on the Soul and Instinctive Principle, and in analogical demonstration of the substantive existence and self-acting nature of the Soul in the latter work, and in the former on account of Müller's affirmation that "it appears to me to be solely the stimulus afforded to the

Reflex Action, &c .- continued.

brain and medulla oblongata by the blood, which immediately becomes oxvdized in the lungs" (MÜLLER'S Physiology, p. 335), upon which the English Translator remarks, "How can the air be drawn into the lungs?"and, in the foregoing Essay, the Author remarks that "a beautiful exemplification (of reflex action of the nervous system) is seen in the newborn infant and other animals breathing with lungs, as I have explained on a former occasion, since here the first impression is transmitted to the nervous centres through the sensitive nerves of the skin in consequence of the contact of cold air with the surface. This is the rationale of the first breath we draw, standing alone in organic life; and the same thing happens, as I also explained, when cold air or cold water, applied to the surface, reproduces breathing in syncope; or, if it be ammonia, &c., applied to the nose, then the sensitive nerves are branches of the fifth pair of cerebral. I will also now say that the function of the pneumogastric nerve is developed for the first time by the first act of inspiration, and fully developed, both as it respects the lungs and the stomach."-Essay on THE Soul and Instinct, p. 57-58 (1849). Also, Skin, Loss of Blood, Syncope, Index II. Also, p. 406, § 638.

explains, through its primary direct development by the Will, the act of roosting and of sleeping in the erect posture, and in a manner analogous to its action upon the sphincter muscles, and employed in demonstrating the substantive existence and selfacting nature of the Soul and Principle of Instinct, p. 890-891, § 1077. Also, Sphincter Muscles, Alteratives, Roosting, &c., Index II.

its physiological laws without any practical use till applied by the Author to Pathology and Therapeutics, p. 106, § 222 b; p. 111-112, § 334 a, b; p. 118, § 234 h; p. 283, § 452 b; p. 285-286, § 455 d-f; p. 296, § 476 c; p. 317-318, § 493 a-d; p. 320, § 494 dd; p. 329-330, § 500 nn; p. 341-342, § 514½ b; p. 515, § 819, 820; p. 579, § 890½ c; p. 596, § 892 b; p. 690-691, § 906 g-910; p. 361, § 530.

for the convenient reference of those who may take an interest in the Author's reclamation (p. 912), he subjoins some of the distinct claims and proofs, which for seventeen years had received universal acquiescence, of his priority in the application of the

physiological laws of reflex action of the nervous system to Pathology and Therapeutics in all its ramifications, and of the dependence of the effects of the Mental Emotions and of the Will upon the same nervous influence, as variously presented in this work, and which application is still limited to his writings, \Diamond 111–113; \Diamond 224; \Diamond 226; \(\phi \) 234 \(a, b; \) p. 113-114; \(\phi \) 234 \(d; \) p. 116-117, \(\phi \) 234 \(f, g; \) p. 236; \(\phi \) 446 \(d; \) p. 262, \(\phi \) 446 \(d; \) p. 282-284, \(\phi \) 451 \(d - 453; \) p. 289, \(\phi \) 475 \(d - 76\) \(d; \) p. 298-299, \(\phi \) 475 \(d - 76\) \(d; \) p. 298-299, \(\phi \) 476 \(d; \) p. 298-299, \(\phi \) 476 \(d; \) p. 298-299, \(\phi \) 476 \(d; \) p. 298-299, \(\phi \) 476 \(d; \) p. 298-299, \(\phi \) 476 \(d; \) p. 298-299, \(\phi \) 477 \(d; \) p. 318 \(d; \) 440 \(d; \) p. 298-299, \(d; \) 476 \(d; \) p. 298-299, \(d; \) 477 \(d; \) p. 298-299, \(d; \) 477 \(d; \) p. 298-299, \(d; \) 478 \(d; \) p. 298-299, \(d; \) 478 \(d; \) p. 298-299, \(d; \) 478 \(d; \) p. 298-299, \(d; \) 478 \(d; \) p. 298-299, \(d; \) 478 \(d; \) p. 298-299, \(d; \) 478 \(d; \) p. 298-299, \(d; \) 478 \(d; \) p. 298-299, \(d; \) 478 \(d; \) p. 298-299, \(d; \) 478 \(d; \) p. 298-299, \(d; \) 478 \(d; \) p. 298-299, \(d; \) 478 \(d; \) p. 298-299, \(d; \) 478 \(d; \) 298 310, \lozenge 484, No. 5; p. 318, \lozenge 493 d; p. 320, \lozenge 494 dd; p. 323–353, \lozenge 499–524; p. 357–358, \lozenge 526 d; p. 361–362, \lozenge 530; p. 515–516, §819 b–820; p. 523, \$\\$827 c; p. 592-593, \\$891\frac{1}{2}k; p. 643, \\$893 a; p. 671-672, \\$903, 904 a; p. 676-677, \\$904 c; p. 679-681, \\$905 a; p. 690-691, \\$906 g; p. 692-693, § 914–921; p. 698–699, § 929– 935; p. 703–710, § 940–952; p. 733

dium of organic structure corresponding changes in the solids and fluids, р. 661-683, § 894-905. Also, Nervous Power, Sympathy, Index I. and II.; REFLEX ACTION OF NERVOUS System, Remedies; Causes, Morbif-IC: BLOODLETTING, LOSS OF BLOOD, LEECHING, THERAPEUTICS, MENTAL EMOTIONS, &c., Index II.

the whole philosophy of the operation of remedial and morbific agents rests upon physiological principles, whether as manifested through the medium of the nervous influence, or in their more independent action upon the organic constitution of parts with which they may come into contact, but differing from the natural stimuli of life not only in the greater manifestations of the nervous influence, but in the alterative effects which it exerts, p. 1, § 1 a; p. 2-4, § 2 a-4 a; p. 36- $\begin{array}{c} 49, \, \lozenge \, \, 63-81 \, ; \, \, p. \, 54-55, \, \lozenge \, \, 109-117 \, ; \, \, p. \\ 58-59, \, \lozenge \, \, 129 \, \, c-i, \, \, p. \, \, 61-73, \, \lozenge \, \, 133-163 \, ; \, \, p. \, \, 101-102, \, \lozenge \, \, 201-202 \, ; \, \, p. \, \, 106 \end{array}$ $\begin{array}{c} -112, \ \, \lozenge \ \, 223-234 \, ; \ \, p. \ \, 121-122, \ \, \lozenge \ \, 237-240 \, ; \ \, p. \ \, 147, \ \, \lozenge \ \, 330 \, ; \ \, p. \ \, 282-362, \ \, \lozenge \ \, 451-530 \, ; \ \, p. \ \, 352, \ \, \lozenge \ \, 524 \, d \, ; \ \, p. \ \, 405-414, \ \, \lozenge \end{array}$ 638–640; p. 541–543, \lozenge 852–854; p. 565, \lozenge 889 f, g; p. 592–593, \lozenge 891 $\frac{1}{2}$ k; p. 661–667, \lozenge 894 b–902 d; p. 679 $\begin{array}{l} -681, \lozenge \ 905 \ a; \ p. \ 703-710, \lozenge \ 940^-952; \\ p. \ 732-736, \lozenge \ 971-980; \ p. \ 745-746, \lozenge \\ 990\frac{1}{2}; \ p. \ 131-132, \lozenge \ 285-288; \ p. \ 398, \end{array}$ \$\delta 626; p. 467, \$\delta 715-719; p. 503, \$\delta 795; Reflex Action, Remedies; Causes, Morbific, Index II.

lying at the foundation of the whole, both of remedial and morbific action, is the mutability of the Organic Properties, which, in being designed for a variety of useful purposes, such as the progressive changes of organization from Infancy to Manhood, gestation, lactation, &c., is necessarily subject to deleterious influences from numerous external and internal causes, while others of a different nature are, for the same reason, and through another great law (the increased susceptibility of morbid states to the action of the latter class in such regulated modes as shall not act profoundly), capable of substituting other pathological changes, which, through another great law (the inherent tendency of the organic properties to maintain their normal state), subside spontaneously into the natural physiological conditions. See VITAL PROP-ERTIES, Index I.; CAUSES, MORBIFIC; Remedies, Therapeutics, the several subdivisions relative to the foregoing topics. Also, PREGNANCY, PARTURI-

II.

Remedial Action—continued.

as displayed by the MENTAL EMOTIONS, whether in their primary connexion with excito-motory nerves alone, or as they give rise to subsequent developments of reflex nervous action (see MENTAL EMOTIONS and DISGUST, Index II.), a perfect correspondence is seen between their effects and those of physical causes, operating alike upon distant parts, or upon the organic constitution of the nervous centres, with both morbific and remedial effect, or as anger and joy may extinguish life in the same sudden manner as a blow upon the head, or through those more complex nervous influences that spring from a blow upon the region of the stomach, or from the shock of a surgical operation, or from drinking cold water in "a heated state of the body," or from hydrocyanic acia; and we unavoidably deduce from the vast variety of effects according to the nature of the emotion or the physical cause, and from the exact coincidences in all their effects, the certainty of an immediate cause appertaining to the nervous system and its endless modifications according to the nature of the remote exciting cause, and looking alone at the mental emotions and those physical causes which are incapable of absorption, and at the diseases which grow consecutively out of each other, we are constrained by all the immense amount of proof which is thus supplied to carry it analogically to the interpretation of the modus operandi of all other remedial and morbific agents through alterative influences of that same reflex action of the nervous system upon all parts beyond the seat of their direct operation, and may finally appeal for the same testimony to the natural stimuli of life, to the blood as it maintains the action of the heart through the same process of reflex nervous influence, and so of the urine and the bladder, the fæces and the sphincter ani, the motions of the iris, the sneezing as induced by snuff and the sun's light, the process of respiration, the act of deglutition, and as some are imitated and others influenced by the will, and as the genital organs unfold the peculiarities of youth, as pregnancy nauseates the stomach and develops the mammary glands, and as parturition starts the flow of milk and leaves the uterine system in a condition to perpetually excite a reflex nervous influence that shall maintain the secretion till men-

Remedial Action-continued.

struation terminates the process, while, also, the stimulus of suction propagates a reflex nervous influence upon the uterine organs, and maintains them in a condition to carry out the final cause of lactation-or, turning to the natural displays of the mind, we may pursue the coincidences be-tween the effects of fear and the contact of cold with the surface of the body in starting on the instant the secretion of urine, or as the odor of food, or its expectation, and its presence in the stomach equally determine an exciting nervous influence upon the salivary glands, and as grief and sneezing alike give rise to tears, and as the sun's light and thinking of the paroxysm occasion sneezing, and as disgust and its recollection, and an emetic, and tickling the fauces alike produce vomiting-and we conclude by commending, in connexion with the foregoing, the following sections, which are mostly relative to the Mental Emotions and the Will, to the candid attention of the Organic Chemist and the impartial Materialist, the former of whom will find these workings of the mind through the nervous influence applied in a great variety of modes as parallel examples with the influences of physical agents on life, and designed to illustrate the modus operandi of morbific and remedial agents of every denomination and shade, and the latter an irrefutable demonstration, as the Author believes, of the substantive existence and self-acting nature of the Soul, p. 89, ϕ 188; p. 95, ϕ 188½ d; p. 104, ϕ 215; p. 107, ϕ 227; p. 108–110, ϕ 228; p. 111, \(\delta 233\frac{1}{2}; \) p. 124-125, \(\delta 433\frac{1}{2}; \) p. 124-125, \(\delta 436; \) p. 128, \(\delta 226; \) 227; p. 230, \(\delta 4226; \) p. 263, \(\delta 446 a; \) p. 281, \(\delta 451 a; \) p. 296, \(\delta 476 c; \) p. 298, \(\delta 476\frac{1}{2} h; \) p. 300-302, \(\delta 479, 480, 481 b; \) p. 312-313, \(\delta 487 - \delta 481 - \delt 487 g, h; p. 314, $488\frac{1}{2}$; p. 323-331, 500 c-o; p. 334-336, 500-513; p. 337, ◊ 514 c; p. 338, ◊ 514 f; p. 340-341, § 514 l, m; p. 356, § 526 c; p. 369 –370, ◊ 565–568; p. 378–381, ◊ 578 d-579; p. 382, ◊ 581 c-e; p. 387, ◊ 4-01, p. 388, \$ 598 d; p. 390, \$ 600 b, 601 c; p. 417, \$ 649 c; p. 478, \$ 740 a; p. 523, \$ 827 c; p. 525-526, \$ 828 a-c; p. 527, \$ 828 e; p. 530, \$ 837 b; p. 534, \$ 844; p. 547, \$ 669, § 863 d; p. 580, § 890½ d; p. 586, §

embraced in Index II.

illustrated in all its phases by the modus operandi of Setons, whose variety of effects manifest all that is essentially relative to the operation of all remedial and morbific agents, physical and mental, and as well in respect to the direct local action of physical causes as to their influences through the medium of reflex action of the nervous system, and exemplifying also the distinction made by the Author between the transient operation of the nervous influence as brought into effect by a single or interrupted applications of remedial and morbific agents and by their undisturbed or but temporarily suspended application, p. 679-681, § 905 a; p. 668-669, § 902 Also, ALTERATIVES; ANTIMO-NY, TARTARIZED; SPHINGTER MUSCLES, ROOSTING, Index II.

if disease be limited to a part on which remedies make their direct impression, the change may then be instituted by the direct action of the cause upon the organic states of the part (the nerves, however, participating more or less, p. 475, § 733 h; p. 483-484, § 746 c), and which may be also true of morbific causes in their production of disease, as seen, in either case, of the curative or morbific effects of caustics, &c.; but it more commonly happens that a reflected nervous influence upon the part is the immediate agent, p. 66-68, § 148; p. 422-423, § 658. Also, Remedies, where this subject is illustrated through numerous references, Index II.; § 514 b.

distinctions to be observed between impressions made on irritability, and common, specific, and sympathetic sensibility, and that the last only is concerned in reflex action of the nervous system, while causes affecting the nervous centres in a direct manner operate primarily through excito-motory nerves alone, p. 671, \$903.

Also, p. 88-90, \$183-188 c; p. 100-103, \$197-204; p. 280-282, \$450-451; Mental Emotions, Reflex Action, individual Passions, Disgust; Brain, Inflammation of, Index II.

Remedial Action-continued.

the fundamental philosophy of disease and its cure, according to the Author's interpretation, is perfectly simple, but involves very complex laws and details, consisting in the former respect of certain changes in the natural physiological conditions, and in the latter of introducing other pathological changes that shall subside spontaneously into the natural conditions, p. 3–4, § 2 *b-d*; p. 331, § 500 *o*; p. 122, § 239, 240; p. 333, § 503–505; p. 352, § 524 *d*; p. 413–414, § 639–640; p. 427, § 667–669; p. 473–474, § 667–669; p. 473–474, § 667–669; p. 473–474, § 674–674, § 6 474, \(\) 733 \(e_1 \) f; \(p_1 \) 531, \(\) 839; \(p_1 \) 535–539, \(\) 847–850; \(p_1 \) 541, \(\) 852–854 \(b_1 \) p. 542, \(\) 854 \(c_1 \) e; \(p_1 \) 545, \(\) 858–859 \(a_1 \) p. 522–593, \(\) 891\(\) 247, \(\) 663, \(\) 697, \(k; p. 662, § 895; p. 663–665, § 897–901; p. 646, § 893 e; p. 652, § 893 l; p. 679, § 905. REMEDIES; CAUSES, Morbific; Therapeutics; Diseases, SELF-LIMITED; SMALL-POX, STRUC-TURE, Index II.

may introduce a variety of pathological changes in any existing disease, either of which may be adequate to the cure, since all remedies operate by establishing morbid states that will soon subside spontaneously, the reflex nervous influence through which the changes are effected being modi-fied according to the special virtues of every remedy (which includes the dose, the nature of the disease, contingent influences, &c.), and hence the reason why loss of blood, cathartics, tartarized antimony, mercury, ipecacuanha, counter-irritants, syncope from mental emotions, &c., will alike remove common inflammation, and certain "specifics" (cinchona, arsenic, guaiacum, colchicum, iodine) specific forms of inflammation when they would increase common inflammation, and cinchona, arsenic, a shock of the mind, and many other things whose chemical and other physical properties are totally different from each other will break up an intermittent fever, and which are also propounded as problems for Organic Chemistry, p. 107–111, \S 227–233 $\frac{1}{4}$; p. 333, \S 503–505; p. 417, \S 649 c, 650; p. 424–425, \S 662 a–e; p. 428, § 671–674; p. 486, § 750 b; p. 542, \$\frac{9}{854}\$ \$c-e\$; p. 480, \quad \frac{9}{10}\$ \$b\$; p. 542, \quad \frac{857}{857}\$; p. 545-546, \quad \frac{9}{859}\$ \$b-861\$; p. 547-550, \quad \frac{9}{863}\$ \$d\$; p. 553, \quad \frac{9}{870}\$ \$aa\$; p. 596-597, \quad \frac{892}{892}\$ \$b\$; c\$; p. 604-606, \quad \frac{9}{892}\$ \$m-p\$; p. 611-612, \quad \frac{9}{892}\$ \frac{1}{6}\$; p. 659, \quad \frac{9}{893}\$ \$q\$; p. 662-665, \quad \frac{9}{896}\$ -901; p. 709, \quad \quad \frac{9}{891}\$ \$b\$; p. 737, \quad \quad \quad \frac{9}{894}\$; \quad \quad \frac{9}{892}\$ \$\frac{1}{892}\$ \$\frac{1}{ v: 6 904 d; 6 1059. time and order of their administration next in importance, and variously exemplified, p. 367, § 556 c; p. 428, § 672; p. 430-433, § 675-676 a; p. 548-549, § 863 d; p. 551-554, § 867-871; p. 570, § 889 n; p. 595-596, § 892 aa; p. 595-598, § 892; p. 600, § 892 d; p. 641-642, § 892 $\frac{1}{2}$; p. 648-649, § 893 g, h; p. 658-659, § 893 p; p. 728, § 964 d; p. 841, § 1058 e. in disease, their action is on common

in disease, their action is on common ground with morbific agents, physical and mental, and the natural stimuli Remedies-continued.

of life, all of which operate with increased intensity in morbid states, and according to the varying susceptibilities, and many remedies, such as tartarized antimony, iodine, ergot, arsenic, &c., which are powerfully curative in their smallest doses, exert no effect in such doses upon healthy organs, and being alike true whether operating upon the organic constitution of parts or through reflex action of the nervous system, a simple exemplification of the whole of which is seen in the failure of a mild solution of the acetate of lead to produce any effect upon the tunica conjunctiva in its natural state, which may quickly remove a mild inflammation of the membrane, or, on the contrary, aggravate to a more intense degree, and connecting this with the curative and morbific effects of a Seton upon the same disease when inserted in the nape of the neck (p. 679-681, $9905 \ a$), we arrive at the combined aspect of the operation of remedies through alterative influences of reflex nervous action, either for good or for evil, upon parts concealed from observation, and upon their organic constitution, and according to the increased and varying susceptibilities arising from disease, as well also according to the natural constitution of the affected parts, p. 3, § 2 $\begin{array}{c} b; \text{p.} 59, \lozenge 129 \ h; \text{p.} 63, \lozenge 137 \ d; \text{p.} 65, \lozenge \\ 143 \ c; \text{p.} 67, \lozenge 149-151; \text{p.} 68, \lozenge 152 \\ b; \text{p.} 120-122, \lozenge 237-240; \text{p.} 332-334, \lozenge 502-506; \text{p.} 339-340, \lozenge 514 \ g, h; \text{p.} \end{array}$ \lozenge 502-506; p. 339-340, \lozenge 514 g. h; p. 352, \lozenge 524 d; p. 415-417, \lozenge 649 a-d; p. 421-423, \lozenge 657-658; p. 435, \lozenge 680; p. 456, \lozenge 698; p. 465-466, \lozenge 715; p. 482, \lozenge 744; p. 509, \lozenge 810; p. 531, \lozenge 838-840; p. 535-539, \lozenge 847-850; p. 541-542, \lozenge 854 bb; p. 545, \lozenge 859 a, b; p. 553, \lozenge 870 aa; p. 607-608, \lozenge 892 a, b; p. 665-671, \lozenge 902 a-m; p. 709, \lozenge 951 b-d; p. 724-726, \lozenge 961 a-e; p. 733-736. \lozenge 974-980. 961 a-e; p. 733-736, § 974-980.

from the foregoing and other premises of a fundamental nature we reach the conclusion that if disease be limited to the part upon which remedies make their direct impression, the salutary influence may be exerted mostly upon the organic states without the intervention of the nervous influence, excepting so far as the nerves constitute a part of the structure, which is particularly true of a few remedies which are intended to be thus restricted, such as caustics, and many applications to cutaneous diseases; but it is in respect to most

Remedies—continued.

remedies, as with most morbific causes in their production of disease in parts upon which their direct morbific impression is made, that, in the former case, the curative effect upon a diseased part as it respects the direct impression is greatly the result of an alterative reflex nervous influence reverberated through the appropriate nerves of the part, or as the remedy or morbific cause may institute sources of reflex action in other parts—all of which may be illustrated by the act of vomiting, whether produced by an emetic, or the gravid uterus, or disease of the kidney, or tobacco applied to the surface, or tickling the fauces, or by a mental emotion, when, in all the cases, a reflex action is reverberated upon the stomach through the excito-motory fibres of the same nerve that transmitted the primary impression to the nervous rinary impression to the herotals centres, p. 66–67, § 148; p. 89, § 188 a; p. 102, § 203; p. 284–287, § 453 c–459; p. 289, § 461; p. 296, § 476 c; p. 302, § 481 b; p. 315–316, § 492; p. 323 -324, § 500 c; p. 327, § 500 i; p. 338, § 514 d; p. 339-341, § 514 g-m; p. 347 314 a; p. 333–341, § 514 g−m; p. 341 -348, § 516 d, Nos. 11-13; p. 416– 417, § 649 c; p. 421–423, § 657 a– 658; p. 475, § 733 h; p. 483–484, § 746; p. 522–523, § 827 b, c; p. 531, § 840; p. 547–550, § 863 d; p. 666– 672, § 992 b–904 b, p. 336, § 514 b.

the foregoing inquiry has been introduced under the Article REMEDIAL ACTION by a reference to certain sections where the modus operandi of Cinchona and Mercury and some other things is shown to depend upon alterative influences of reflex nervous action, and we may now look at other sections relative mostly to Tartarized Antimony, partly for the purpose of illustrating what is known as the cu-mulative effect of remedies (that is to say, when their effects are not particularly manifested until after a number of doses, and there may be then a sudden and powerful display of a curative or morbific nature), and in part as a farther demonstration against the doctrine of operation by absorption, since, if it be allowed that the medicine is absorbed, all its influences upon disease may be shown to depend on its action upon the stomach and consequent reflex actions of the nervous system-for if the doctrine of absorption were true, it should not be necessary to carry its small therapeutical doses to near the point of nausea to subdue inflammations and febrile exRemedies—continued.

citements, while it is one of the most familiar facts that the dose must generally be gradually increased, often from the sixteenth of a grain to half a grain or more, to maintain the effect upon disease, the skin, general excitement, &c., which was originally produced by the smallest dose; but so long as the sixteenth or the fourth of a grain manifest an approximation to the point of nausea, it will as effectually break down arterial excitement, produce perspiration, and overthrow pneumonia as effectually as when two grains may be necessary to the same amount of impression upon the stomach, and without which the symptoms will again increase-and also exemplified to the same effect by the manner in which it overcomes croup, in which affection no relief will follow till it produce some degree of nausea, whatever the quantity exhibited, but as soon as its nauseating influence is felt, the well-marked symptoms of the disease begin to yield, and rapidly so when vomiting ensues, showing that the whole effect is due to the influence upon the stomach, which determines the act of vomiting -and, finally, according to the doctrine of absorption, there should be no necessity whatever between this gastric irritation and the salutary effects of the remedy, and the only rule should be to introduce a certain quantity into the circulation, p. 344-345, tity into the circulation, p. 344–349, \$516 d, No. 6; p. 351, \$524 a, No. 1; p. 355, \$526 a; p. 356–357, \$514 b, c; p. 365–368, \$549–559; p. 431, \$675; p. 486, \$750 b; p. 530–533, \$837 b–841; p. 547, \$683 d; p. 556–557, \$873; p. 567–569, \$889 l-mm; p. 612–613, \$892\frac{1}{2} a, b; p. 634, \$892\frac{1}{2} b; p. 638–640, \$892\frac{1}{2} c; p. 641 6 899\frac{1}{2} i; p. 666–670 g; p. 641, \lozenge 892 $\frac{4}{5}$; p. 666–670, \lozenge \lozenge 902 b-m; p. 675–676, \lozenge 904 b; p. 833, \lozenge 1057 h; p. 850–851, \lozenge 1059.

physiological distinctions between Cathartics and Emetics, and corresponding effects of Mental Emotions, and other relative considerations, and as acting through the medium of the nervous influence variously modified according to the nature of its exciting cause, p. 547-550, \$ 863 d; p. 631-632, \$ 892\frac{3}{2} b. the usage of reasoning from the results of experiments with remedies upon man in health to their effects upon morbid conditions must be included among the important obstacles in the Remedies-continued.

way of philosophical as well as practical medicine on account of the vital changes in the diseased parts, and the alterative influences of these changes upon the susceptibilities of all parts (p. 535-539, § 847-850, and Law of ADAPTATION, Index I; DISEASES, SELF-LIMITED, second subdivision), and especially from similar experiments upon animals, who differ not only from man, but each species from others in their vital constitu-170m 6thers in their vital constitu-tion, p. 3, \(\delta \) b; p. 63, \(\delta \) 137 \(d; \phi \), 65, \(\delta \) 143 \(c; \phi \), 67, \(\delta \) 149-151; p. 68, \(\delta \) 152 \(b; \phi \), 73, \(\delta \) 163; p. 122, \(\delta \) 240; \(\phi \), 148, \(\delta \) 334; p. 430-433, \(\delta \), 675-676 \(a; \phi \), 435, \(\delta \) 680; p. 456, \(\delta \), 698; p. 465-466, \(\delta \), 715; p. 482, \(\delta \), 744; p. 498, 784 \(a; \phi \), 535-539 \(\delta \), 847-850, \(\delta \), 847-850. 837 cc-840; p. 535-539, \Diamond 847-850; p. 541-542, \Diamond 854 bb; p. 545, \Diamond 859 a, b; p. 548-549, \Diamond 863 d; p. 607-608, $\S 892 \ a, b$; p. 612, $\S 892\frac{1}{2} \ a$; p. 623, § $892\frac{2}{3}$ c; p. 676, § 904 c—and when injected into the circulation, they must of necessity give rise to some of the effects, among a greater variety, as when administered by the stomach, p. 529-533, § 836-841, though these may have been as much overrated as certain supposed effects of quinine, p. 603, \S 892 k, and which is rendered the more probable by the statements of other distinguished observers as to the effects of morbific agents when injected into the circulation, p. 482, § 744; p. 527-528, § 830-831; p. 932, ◊ 1088 d.

their operation by absorption, as generally interpreted, very embarassing to a distinguished advocate thereof on account of a perplexing difficulty offered by the portal vein, p. 527, §

829.

as disease consists of a succession of changeable pathological causes, whether it terminate favorably or fatally, remedies operate like morbific causes, and for other reasons assigned, but with the difference that the former are less profoundly morbific, and substitute pathological states that are readily capable of subsiding spontaneously through the inherent tendency of the properties of life to return to their natural states, and therefore by no possibility can they transmute the morbid into a healthy condition, which is alone the work of elaborate processes of organization-all of which are impossible problems for Chemistry and Physics, especially in connexion with the variety of means that will subdue a given form of disRemedies-continued.

ease, the necessity of accurate doses, and the importance and the ability of projecting a plan of treatment consisting of a variety of means to be applied in an exact consecutive order to fulfill the intention of introducing a succession of pathological changes of which each one is necessary to the next in order, from the abstraction of blood to the cathartic, then to the antimonial or mercurial alterative, then a blister, mayhap quinine, or arsenic, or guaiacum, or colchicum, or iodine, &c., and where there are but shades of difference in the morbid stateswhile, also, any given form of disease, such as intermittent fever, may be arrested by cinchona, or arsenic, or cobweb, or an emetic, or loss of blood, or a mental emotion, and syphilis by mercury, or iodine, or bromine, &c., each one a simple element, but having physical properties and chemical relations very widely different, and which may be just as consistently assumed to form salts with each other as that they will alike cure the same conditions of disease by chemical action upon the tissues, or upon the blood or miasms, and considering, too, that less than a grain of quinine or of arsenious acid will subdue an intermittent fever, or that quantity of the latter break up a chronic cutaneous disease over the whole surface of the body-but thus showing that the substitution of a large variety of pathological changes corresponding with the alterative virtues of the several remedies, respectively, is capable, each one, of placing the more profoundly morbid states in the way of spontaneous subsidence, so that, whether it be a simple intermittent fever or complicated with cutaneous eruptions, when the impression is made that will enable Nature to throw off the fever, the same artificial change may equally induce, upon the same recuperative principle, the disappearance of the chronic affection of the skin, p. 67, § 149-152; p. 87, § 177skin, p. 67, \lozenge 149–152; p. 87, \lozenge 177–182; p. 122, \lozenge 237–240; p. 147, \lozenge 330; p. 333, \lozenge 503; p. 417–418, \lozenge 650; p. 424, \lozenge 662; p. 426, \lozenge 666; p. 428, \lozenge 672; p. 430–433, \lozenge 675; p. 438, \lozenge 684, No. 9; p. 470–471, \lozenge 729–731; p. 473–474, \lozenge 733 e; p. 486, \lozenge 750 b; p. 487–488, \lozenge 756; p. 535–539, \lozenge 847–850; p. 541–545, \lozenge 854–860; p. 547–549, \lozenge 863 d; p. 551–554, \lozenge 867–871; p. 561–562, \lozenge 888 a–d; p. 596, \lozenge 892 b, e; p. 606, \lozenge 892 p; p. 637, \lozenge 892\$ d, e; p. 666, \lozenge 892 p. 637, § 892\frac{4}{5}d, e; p. 648-649, § 893

Remedies—continued.

g; p. 661–670, § 894–902; p. 679–683, § 905 a, b; p. 696, § 926.

it follows, therefore, that one remedy prepares the way for another, and in prepares the way for another, and in a variety of respects, p. \$67, \$56 c; p. 423, \$659; p. 424, \$662 b; p. 428, \$672; p. 545, \$859 b; p. 551-552, \$867-868; p. 554-556, \$892; p. 561, \$888; p. 595-600, \$892 a-d; p. 658, \$893 p; p. 664-665, \$900-901; p. 843, \$1058 f; p. 844-847, \$1058 p; p. 844-847, \$1058 p; p. 644-647, \$1058 p; p. 644-647, \$1058 p; p. 844-847, \$1058 p; p. 845-847, \$105 $1058 \ m-q$.

the Author anticipates an assumption, when the doctrine of the operation of remedial and morbific causes, physical and mental, through reflex and direct action of the nervous system, can no longer be resisted, that the nervous influence is the chemical agent which does the work, and answers that the obstacles will be in no respect removed, for, in this special respect, in carrying out the Chemical hypothesis, there should be no varieties in results corresponding to the nature of the remote exciting causes, but the nervous influence should always act in conformity with any special agent employed in the Laboratory, and therefore produce uniform phenomena, at least in any given part, as when an acid unites with an alkali, or platina predisposes oxygen to unite with hydrogen, while, on the contrary, the Author's doctrines conform to the very maxim of the Lawqui facit per alium, facit per se. As

their effects owing to the mutability of the properties of life, which is designed for useful purposes. See Remedi-AL ACTION; RECUPERATION, LAW OF, Index II.; VITAL PROPERTIES, In-

dex I.

are abortive whenever the morbid changes transcend the recuperative law, p. 420, \$ 654 a; p. 552, \$ 868 b; p. 661, mottoes; p. 728, \$ 964 c. Also, RECUPERATION, LAW OF, Index II.; VITAL PROPERTIES, Index I.

the great law of recuperation demonstrable in the self-limited diseases, and in animals, p. 531, § 839; p. 544 -545, \$858, 861; p. 551, \$863 h-and by the simple system of watching or expectant plan, p. 543, § 855-857; p. 558–559, § 877–881.

hence, in a general sense, the most important remedy in the treatment of diseases, acute and chronic, is a properly regulated diet-a limitation to farinaceous fluids in the early stages, at least, of the former, while in the latter, the circumstances of each case

Remedies-continued.

must determine the choice-there being ingrafted upon the constitution of the whole animal kingdom a prin-'ciple, latent in health, but which enables them in disease to bear an abstinence that will alone surmount the most formidable conditions, but which would probably be often fatal in the natural state of the system-and in man the principle is the same as that which renders the most active remedies curative instead of morbific, p. 63, § 137 b-e; p. 67, \lozenge 149; p. 69, \lozenge 156 b; p. 538–540, \lozenge 847 g–848; p. 543, \lozenge 855–856; p. 551, \lozenge 863 h; p. 558–559, \lozenge 879–883 b; p. 600, \lozenge 892 d; p. 736, \lozenge 980. Also, Adaptation, Law of, Index I.; RECUPERATION, LAW OF, Index II.

by healing a primary disease which had given rise to sympathetic developments of disease in other parts, the sympathizing ones often recover not only as a consequence of the subsidence of the morbific reflex nervous influence, but the abatement of the primary affection may become also a source of salutary sympathetic influences upon the secondary developments; or, one disease supervening as a sympathetic result of another may be the means of reflecting, after the manner of counter-irritants, a salutary alterative reflex action upon the trary afterance reflex action upon the primary affection, p. 65–66, § 143 c; p. 67, § 148; p. 351–352, § 524 c; p. 360, § 528; p. 421–422, § 657; p. 506, § 804; p. 539, § 848; p. 570, § 889 n; p. 652–654, § 893 n; p. 679–681, § 905 a, b; p. 592, § 891½ k; p. 666, § 902 b. Metastasis, Ind. II.

often bring organs not affected by disease, through reflex nervous action, particularly the skin, into a condition which becomes the exciting cause of other reflex influences that fall upon diseased organs with a salutary effect. See this subdivision under RE-

MEDIAL ACTION, Index II.

operate progressively or abruptly, according to the intervals of application, when, in the former case, the reflex nervous influence is maintained in unceasing action by a succession of different remedies, or doses of the same remedy, at short intervals, and even in the latter case, as after the administration of an efficient emetic or cathartic, the reflex influence is kept up by the impression made on the gastro-intestinal mucous tissue with alterative effect for some hours after their more manifest effects are over, and the same principle holds in Remedies—continued.

respect to mental emotions-and farther, that remedial influences are exerted and maintained by the smallest doses of the remedies designated by the Author as Alteratives, is evident not only from the abatement of symptoms, but from the vomiting which will often follow after the first few doses of an eighth of a grain of tartarized antimony or a grain of ipecacuanha-and so of mercury, arsecacuanna—and so of mercury, arsenic, iodine, quinine, &c., p. 111, § 233\(\frac{1}{2}\), 233\(\frac{1}{2}\), 233\(\frac{1}{2}\), 232\(\frac{1}{2}\), 232\(\frac{1}{2}\), 232\(\frac{1}{2}\), 232\(\frac{1}{2}\), 232\(\frac{1}{2}\), 233\(\frac{1}{2}\), 9503-506\(\frac{1}{2}\), p. 339, § 514\(\frac{1}{2}\), \$\(\frac{1}{2}\), \$\(\frac{1}\), \$\(\frac{1}{2}\), 592–593, \S 891½ k; p. 599–600, \S 892 d ; p. 646–649, $^{\circ}$ 893 e-h ; p. 661–663, $^{\circ}$ 894–896 ; p. 668–670, $^{\circ}$ 902 g-m ; p. 675–676, $^{\circ}$ 904 b ; p. 679–681, $^{\circ}$ 905 a. Also, ALTERATIVES, SPHINC-TER MUSCLES, ROOSTING, MIASM; HY-DROPHOBIA, VIRUS OF; MENTAL EMO-TIONS, Index II.

a single remedy may be adapted to a large variety of pathological conditions, and these may exist simultaneously in different parts as the sympathetic results of a single disturbance, and associated also with idiopathic fever, and the remedy may be adequate to the removal of all the functional lesions, or preparatory of the whole to the favorable action of another remedy of opposite virtues, and upon which the cure may ultimately depend-thus showing, also, by the variety of means which individually may arrest very complex states of disease, that our doctrine of alterative influence of reflex action of the nervous system, modified according to the nature of the remedy, and the harmonizing influences of coexisting diseases upon each other through the medium of the same reflex action as brought into reciprocal operation by the several affected parts, and the substitution of pathological states with a disposition to subside spontaneously, can alone explain the phenomena with any consistency with the immediate facts and with those which relate to Chemistry and Phys-Annel relate to Chemistry and Thysics, p. 63, § 137 c-e; p. 65-67, § 143 b, c-148-151; p. 298, § 476½ h; p. 304, § 481 g; p. 309-310, § 484 b, No. 5; p. 337, § 514 b, c; p. 361; § 529 b; p. 367, § 557 a, b; p. 426, § 666; p. 430-433, § 675; p. 465-466, § 715; p. 479-480, § 741 a, b; p. § 715; p. 479-480, § 741 a, b; p.

the fluid products of glandular organs, sweat, gastric juice, &c., and all the solids, on common ground as it respects their dependence upon organic actions and their relations to the nervous system, though in the normal state the fluids manifest far greater influences of the nervous power than the composition of the solids, and the glandular fluids more so than the membranous; ut supra, and Organic Compounds, Vital Properties, Or-

GANIC LIFE, Index I.

the apparently endless variety of organic fluids as well as solids in plants and animals, and each one forever the same in any given part in its perfect state, and mostly composed of four elements, their ternary or quaternary combinations, ratios and diversities in their modes of union, their dependence in animals for their perfected condition upon modifying influences of the nervous system, while they have no such tributary aid in plants, and their natural and morbid fluctuations in animals under the influence of direct and reflex action of the nervous system as brought into effect by mental emotions or physical agents, and according to their precise nature, contradistinguish the laws of organic from those of inorganic bodies and a fundamental distinction drawn between what belongs to organic life and what is referable to its influences by the nervous system, p. 21, \Diamond 22; p. 23–26, \Diamond 37–48; p. 27–28, \Diamond 52–53;

Secretion and Excretion-continued.

p. 30, § 58; p. 193, § 356 a; p. 220– 227, § 409 b-411; p. 230-232, § 422 b-424; p. 262-263, § 446 a; p. 289, \$\delta 461; p. 313-315, \$\delta 488-489; p. 317 -318, \$\delta 493; p. 335-336, \$\delta 512 a, b;\$ p. 355, § 526 a; p. 483–484; § 746 c; p. 547–548, § 863 d; p. 563–564, § 889 a; p. 630–632, § 892‡ b, c; p. 668-669, § 902 g; p. 704, § 943 a; 804-805, § 1040; p. 866-867, § 1067 a; § 221½, 399, 456 a, 478 b.

by now taking in connexion what the Author has said under the sections in the two preceding subdivisions of the influences of the reflex action of the nervous system upon the secreted fluids, there may be found, at p. 478-480, § 740-741 (where the Author presents an example, for illustration, from the humoral pathologist), the whole philosophy distinctly and briefly presented relative to the part which the nervous influence takes in organic processes, the products being generated by the organic mechanism through its own inherent properties, p. 55, § 113-117; p. 58-59, § 129 ci; while the nervous influence, in its morbific aspect, and whether excited by physical or mental causes, so modifies their condition that they elaborate morbid instead of natural products; and, turning to the example of the Seton at p. 679-681, \$ 905 a, there will be found, in an equally succinct manner, the whole philosophy of the alterative influence of reflex action of the nervous system as the medium through which all the modifications of secreted products, as set forth under the sections embraced in the foregoing subdivisions, are brought about, and as exemplifying all that is ever concerned in the modus operandi of remedial and morbific causes, upon parts beyond the seat of their direct operation-while, also, even animal heat is on the same common ground with other secreted products, and its generation, therefore, is alike influenced by reflex and direct action of the nervous system. See, also, NERVOUS SYSTEM, Index II., p. 1029, subdivision upon Animal Heat.

considered by the Author as "fully settled by experiments" made by A. P. W. PHILIP, that "the power of secretion is independent of, though influenced by the nervous system," as appears in his Reports of the same in London Philosophical Transactions for 1815 and 1817, and to which there are summary references at p. 314-315, § 489; p. 317–318, § 493 a-dSecretion and Excretion-continued.

and, therefore, long antecedently to the suggestions upon the same subject by Henle, Donders, Ludwig, &c., while, also, Bichat had arrived at the same opinion without the aid of experiment, p. 270, § 447 d.

uses in diseases of fluid products, being different according to the nature of each, p. 231, § 422 c; p. 232–234, § 427–428; p. 450–451, § 691, 692; p. 471, § 732 b; p. 473–474, § 733 e; p. 546–551, § 862–864; p. 637, § 892\$ d; p. 639, $0.892\frac{4}{5}$ g; p. 647, 0.893 f. experiments by several hands proving that it does not operate by absorption, but, like the hydrophobic virus, by morbific influence of reflex action of the nervous system instituted by the bitten part, p. 319, § 494 b-dd; p. 348, § 518 a, b; p. 525-526, § 828 a-d. Also, Hydrophobia, Virus of, Index II.

SETON,

its modus operandi both locally and through alterative influence of reflex action of the nervous system, exemplifying the whole philosophy that is ever concerned in the operation of remedial and morbific agents, p. 679-681, § 905 a—originally set forth in Essay on the "Modus Operandi of Remedies" (1842).

SHAME

doubtless awakens the consciousness of an internal monitor distinct from the corporeal fabric-but how does it betray itself in the crimsoned cheeks, or, if blended with a little Fear, in the trembling muscles, the drops of sweat, and the flow of urine, unless through that amazing principle the nervous influence, which may strike us dead in an instant when Joy and Anger make their sudden and violent demonstrations, or as blows upon the epigastric region, and surgical operations, and the bite of venomous serpents, and hydrocyanic acid, and the respiration of chloroform, will do the same—and thus, also, as unmingled or compounded with other emotions, Shame exemplifies the manner in which remedial and morbific agents of a physical nature, and according to their simplicity or complexity and the nature of each, will institute corresponding influences of reflex nervous action - or turning to Fear alone, there may be seen in its displays of the nervous influence a near coincidence with that universal alterative impression which a single morbific or remedial agent may exert, as witnessed in the production of fever, and in its cure by loss of blood or an emetic, or, to complete the coincidence, by a mental emotion, p. 95, \lozenge 118½ d; p. 107–111, \lozenge 227–233½; p. 245, \lozenge 440 e, No. 14; p. 324, \lozenge 500 e; p. 327–328, \lozenge 500 j, k; p. 332, \lozenge 501 e; p. 327–328, \lozenge 500 g, k; p. 332, \lozenge 501 e; p. 333, \(\delta 503 \); p. 339-341, \(\delta 514 \) g-m; p. 631-632, \(\delta 892\frac{3}{4} \) b; p. 661-663, \(\delta 903\frac{3}{4} \) 894-896; p. 665-670, § 901-902; p.

it has never been shown, however much assumed, that the human Skin will absorb extraneous substances, not even water, as Magendie decides, and the experiments relative to opium, the wourari poison, the virus of serpents, hydrocyanic acid, &c., go to our present purpose; and this failure of experiments to prove absorption is farther shown by a forced analogy drawn from the supposed absorption of water by the Skin of Lizards; for, however the general analogies obtain in respect to great fundamental laws, they are quite liable to fail as regards certain special functions, and it would be an equal ground of reasoning with the foregoing to the Skin of man from animals that respire by that organ, or others by whom it is periodically shed, or, in other respects, from the regeneration of the Lizard's tail, &c., p

the effects upon, by narcotization, and of acetic acid applied to the mouth and skin of eviscerated frogs, employed in interpreting the operation of remedies upon internal parts when Skin-continued.

applied to the skin, through alterative influences of reflex nervous action. See Volkman, Index II.

some parts of, more susceptible of those impressions which occasion morbific influences of reflex action of the nervous system than other parts, p. 61-62, \(\phi\) 133-136; p. 415-416, \(\phi\) 649 b; p. 695, \(\phi\) 924, also Amenorrhea, Leeching, Index II.—which reflects light upon Brown-Séquard's observations upon epileptiform convulsions, as produced by irritation of particular parts of the skin, p. 802, \(\phi\) 1037 a.

its eruptive diseases often occasioned by a morbific reflex action of the nervous system instituted by disorders of the alimentary canal, as manifestly the case after a debauch, and as seen, also, in the immediate subsidence of the cutaneous affection under the influence of an emetic or cathartic, which not only arrest the morbific cause, but determine a curative reflex action; and which serves as an index to the philosophy of the origin of numerous chronic eruptions, and of their cure by gradually alterative remedies operating through the same reflex nervous influence-or, again, a supervening eruptive disease may react upon and relieve the internal affection; and when we associate with the foregoing the heterogeneous variety of things that will alike cure the same chronic eruptions, whether internally or externally applied (even more various in their physical properties than the remedies for intermittents), and other analogous facts which meet our attention on every hand, the philosophy of Vital Solidism, wielding the magic power of the nervous system, falls with a crushing weight upon the factitious analogies borrowed from the precise laws of the inorganic world, p. 352, § 524 c; p. 359, § 527 a, b; р. 669–671, § 902 i, m; р. 673, § 904 b, also, Оргим, HUMORAL PATHOLOGY, REMEDIAL AC-TION, Index II .- and the constitutional effects of small-pox, measles, and scarlatina probably depend upon a morbific reflex nervous influence instituted by the alimentary mucous tissue, as denoted, also, by the primary appearance of the eruption in the fauces-excepting as inoculated smallpox would involve a primary reflected influence of the nervous power upon the mucous tissue (instituted by the artificial pustule), and thence a reflected action upon the skin as the exciting cause of the general erupSkin-continued.

Sympathies of Compound Organs with each other, p. 361-362, § 529-530.

Sympathy, Remote and Contiguous, terms of brevity, whose generic name is

Sympathy, &c .- continued.

derived from that of the nerve which, with the pneumogastric, is the principal channel through which reflex actions of the nervous system are conducted (and is thus employed by Müller and other Physiologists, p. 349, \$ 520; p. 352, \$ 524 c, &c.), and the only distinction between them consists in the greater limitation of the former to the cerebro-spinal axis as the central parts for reflected actions, while contiguous sympathy is manifested more particularly through local centres, which may consist of either the ganglia of the sympathetic nerve, or of plexuses of nerves, or of some portion of individual nerves (the last of which the Author, as will be seen, had considered probable, and which has been recently experimentally ascertained), but is, doubtless, always associated more or less with reflex actions conducted through the brain and spinal cord, as conspicuously manifested in the action of Vesicants and Leeches when applied over some internal inflammation, and, in its more circumscribed aspect, in the examples of dilatation of the iris at p. 673-674, § 904 b, and of the sciatic nerve at p. 838, § 1057½—and it now remains only to refer the inquirer for the practical applications of remote sympathy to the sections embraced under the Article Reflex Action of the Nerv-OUS SYSTEM, Index II.; while he will find under the following sections the combined aspects of reflex action as conducted more or less through local centres of the nervous system, and its main centres, with various illustrations, and designated by the old name of Contiguous Sympathy, p. 287-OT CONTIGUOUS SYMPATHY, P. 287–289, \lozenge 458–461; p. 293, \lozenge 473 c; p. 294, No. 5; p. 312, \lozenge 487 g; p. 319, \lozenge 494 dd; p. 321, \lozenge 497; p. 323, \lozenge 499 a; p. 334, \lozenge 507; p. 343–344, \lozenge 516 d, Nos. 3–5; p. 345–346, \lozenge 516 d, Nos. 7–9; p. 349, \lozenge 520–522; p. 353, \lozenge 524 d, Nos. 4–7; p. 642–644, \lozenge 683 g–g–g; p. 646–653 \lozenge 893 g–g–g; p. 646–653 \lozenge 893 g–g–g. ♦ 893 a-c; p. 646-653, ♦ 893 e-n; p. 803, § 1038; p. 838, § 1057½.

SYMPATHY, CONTINUOUS,

an old designation, and liable to the objection of being confounded with the laws of reflex action, and therefore the Author proposed the substitution of continuous influence (p. 322, § 498 a)—is common to Plants as well as Animals, but differing in the latter not only according to the nature of tissues (being far more strongly pronounced in some than in others, as in the veins and lymphatics), but by the

Sympathy, Continuous-continued.

incorporation of the nerves in all animal tissues (p. 483-484, § 746 c), and exemplified by the prick of a pin when the resulting inflammation extends in a continuous manner from point to point, or as seen in erysipelas, but sometimes remarkably limited in its progress, as at the divergence of veins, and shown, also, in a variety of other ways, as by the cathartic effect of croton oil applied to the tongue, by leeching the anus, by suppositories, and more or less by cathartics, especially such as act upon the liver, by the manner in which chewing tobacco, &c., excites the salivary glands, or irritation of the eye the lachrymal, &c., and is an element in venous circulation, but which, in all the cases, and according to the nature, extent, and force of the impression that may be continuously made, whether inflammatory, or simply an irritative, or a sedative effect, and according, also, to the nature of the tissue and of the compound organ, gives rise to a corresponding reflex action of the nervous system, which may fall upon various distant parts, and with all the variety of effect as set forth under Articles Reflex Action and Nervous Power, or may be directed upon the part which is the seat of the continuous affection and increase its extension and force, and thus multiply the force of the reflex action, and institute new circles and other influences upon other organs, p. 58, § 129 c, f; p. 64, § 141 b; p. 66-67, § 148; p. 209–210, \(\delta 887; \) p. 321, \(\delta 494 e; \) p. 322–323, \(\delta 498; \) p. 343, \(\delta 516 e; \) p. 350, \(\delta 523, \) Nos. 6, \(7; \) p. 351, \(\delta 524 a, \) No. 2; p. 355–356, \(\delta 526 b, c; \) p. 465–466, \(\delta 715; \) p. 475, \(\delta 733 h; \) p. 483-484, § 746 c; p. 506, § 803, 804; p. 524, § 827 e; p. 526, § 828 d; p. 563–564, § 889 a; p. 694–695, § 923. Also, Oil, Croton; Leeching, Suppositories, Heat, Circulation of the Blood, Index II.; Ve-NOUS TISSUE, VENOUS CONGESTION, Index I.; p. 665, § 902 a. Note U.

SYMPTOMS, MORBID,

distributed into five groups—1st, vital signs; 2d, relative to the instruments of disease, but independent of structural changes; 3d, relative to the secretions and excretions; 4th, of the foregoing nature, but determined or modified by changes of organization; 5th, of a physical nature depending on changes of structure, accumulated fluids, &c.—the first three being primary, the last two secondary, p. 435, § 681 a.

Symptoms, Morbid-continued.

See Reflex Action, Mental Emotions, the Individual Passions, Index II.

the curative effects of remedies upon the seat of their direct operation, particularly in morbid states of the stomach, is less owing to their direct alterative action than to a reflex action of the nervous system—and this corresponds with the morbific effects of many causes of disease when manifested in the seat of their direct operation, as seen particularly of cold and miasms -and problems of the same and more complex nature are involved in the salutary effects of exercise, change of air, &c., in dyspepsy, whoopingTherapeutics—continued.

cough, phthisis, &c .- in all of which cases, as well also in all that concerns the operation of remedial and morbific agents beyond the seat of their direct action, the effects are owing to reflex influence of the nervous system-and for these several specifications see REFLEX ACTION, REMEDIAL ACTION, Sympathy, Remedies, Alteratives, BLOODLETTING; CAUSES, MORBIFIC, WHOOPING-COUGH, PHTHISIS, EXER-CISE, FRICTION, COLD, MIASM, SHOW-ER-BATH, SEA-SICKNESS, MENTAL Emotions, Index II.; NERVOUS Pow-ER, Index I. and II.

diseases often subside spontaneously as others spring up sympathetically upon them, the nervous influence being the exciting cause in all the cases so far as any influences are sustained by the pathological conditions, the philosophy being also the same as when vesicants produce inflammation of the bladder, or aggravate or remove inflammations of other parts—the only difference between the morbific and curative effects being, that the reflex action of the nervous system is either more profoundly morbific or differently modified in one case than in the other-but, as it is the general tendency of diseases to generate others and to aggravate antecedent ones, and as the most favourable results of these reactions of the nervous influence are rarely salutary in the end, it is a great error to promote the continuance of natural diseases in the very slender hope that a greater evil may be thus overcome or an apprehended one avoided (not even the hemorrhoidal flux, though arresting it by a removal of its remote cause); and, although artificial diseases may be instituted in the skin by agents of transient effects with a view to salutary influences upon internal diseases, they cannot be set up in other organs, particularly the alimentary canal, but with an adverse effect—and it is upon this same principle that the habitual use of small doses of cathartics in a large proportion of dyspeptic cases overcomes constipation without detriment, while the indigestible food which is used for the indigestible rood which is used for the same purpose proves morbific, p. 67, § 148; p. 351–352, § 524 b-d; p. 360

WARM BATH,

its effect in relieving pain and promoting sleep, the result of a sedative reflex action of the nervous system determined upon the nervous mechanism, p. 589, § 891 p, exemplifying, also, the modus operandi of Narcotics, Antispasmodics, &c., and the great recuperative law, p. 592-593, 0 891 $\frac{1}{2}$ k; p. 681-683, 0 905 b; p. 838, 010572-while it equally extends its influence to all other parts through the same medium, operating according to the nature of the part and existing susceptibilities, being like cold in its action upon the kidneys a stimulus to the bladder, by which it will immediately determine its contraction, which is one of the numerous simple processes that interpret the modus operandi of morbific and remedial agents, and its relief of diseases according to temperature and the activity or indolence of morbid states and the nature of the affected part, presents a parallel with the effects of internal remedies according to their doses and analogous conditions, and

Warm Bath-continued.

thus farther illustrates the Author's doctrine of morbific and remedial action as applied to all cases through the medium of reflex nervous influence, and of his doctrine of modification of that influence according to the nature of its exciting causes, *ibid.*, and Skin, Cold, Kidney, Sedatives, Opium, Poultices and Hot Fomentations; Recuperation, Law of; Respiration, Food, Exercise, Structure, *Index II.*

WATER, HOT,

its effects in its action upon the stomach in producing free perspiration, like the glow and moisture of the surface which often spring from the first contact of food with the stomach, or as the odour or expectation of food increase the flow of saliva, or as the contact of cold air with the surface starts the secretion of urine, or as fear, and anxiety, and jealousy will do the same along with perspiration, or grief the tears, and all depending upon reflex or direct action of the nervous system, illustrates the perpetual operation of that influence in its most simple conditions in modifying the action of the secerning vessels, and the whole collectively stretch their con-clusive analogies to the corresponding effects of emetics, cathartics, loss of blood, &c., and through their analogies, and independently of our other accumulated proof, to the various other simultaneous effects that are incident to morbific and remedial agents in their action upon parts beyond the seat of their direct operation, and thus also show how the nervous influence is variously modified in all the cases according to the nature of its exciting causes, and that the changes in the secretions are owing to these variously modified conditions, and proclaim the substantive existence and self-acting nature of the Principle in which the Mental Emotions originate-and now leaving the stomach for the rectum, and considering how the sphincter muscle is held in contraction by a perpetual determination upon it of the nervous influence, and that the natural peristaltic movements depend, also, upon reflex actions of the nervous system that have their centripetal origin in all parts of the gastrointestinal mucous tissue, as much so as the muscles in deglutition in a more circumscribed portion, or all things that produce vomiting in the mucous lining of the stomach, and that it is through the same causation

Water, Hot-continued.

that an enema of warm water increases the intestinal movements, we become assured that their greater acceleration, and other attendant effects that result from the addition of salt, or soap, or aloes, &c., to the simple enema, depend equally upon the same reflected influence, and equally, therefore, when cathartics are administered by the stomach, since, also, if the enemas do not increase the peristaltic movements by their absorption, but, like the natural movements and the contraction of the sphincter muscle, and the act of swallowing, and the vomiting from drinking warm water or tickling the fauces, or a mental emotion, through the nervous influence, then, since there is no absorption, must all the other effects, curative or morbific, be equally due to that influence-and thus, finally, a broad ground of exact analogies is obtained for going in pursuit of an apparently endless variety of other concurring facts that are relative to the modus operandi of all other remedial and morbific agents, physical and mental, p. 107-111, \(\dagge 226-233\) ; p. 230-232, p. 107–111, \(\) 226–233\(\); \(p. 230–232\), \(\) \(422 \) \(b-424\); \(p. 289\), \(\) \(461\); \(p. 296\), \(\) \(476 \) \(c_1 \) \(P. 301–302\), \(\) \(481 \) \(b_1 \); \(p. 335-336\), \(\) \(512 \) \(a_1 \) \(b_1 \); \(p. 339–340\), \(\) \(514 \) \(b_1 \); \(p. 351\), \(\) \(524 \) \(a_1 \), \(0.1 \); \(p. 451\), \(\) \(692 \) \(a_1 \); \(p. 478-479\), \(\) \(740 \) \(a_1 \); \(p. 483-484\), \(746 \) \(c_1 \); \(p. 534\), \(\) \(844\); \(p. 563-565\), \(\) \(889 \) \(a_2 \) \(a_2 \), \(c_1 \); \(p. 634\), \(\) \(892\) \(b_1 \); \(p. 662-683\), \(\) \(896 \) \(p. 667-670\), \(\) \(902 \) \(d_2 \). 663, § 896; p. 667–670, § 902 *d–i*; p. 704, § 943 α; p. 866–867, § 1067 a. Also, Reflex Action, Remedial ACTION, SECRETION AND EXCRETION, SWEAT, BILE, WEEPING, FEAR, DIS-GUST, CATHARTICS, EMETICS, ALTER-ATIVES, BLOODLETTING, LEECHING, Suppositories; Sympathy, Continu-OUS; SOUL AND INSTINCTIVE PRINCIPLE, Index II.

WEEPING.

the result of an emotion, however violent, that rarely produces much disturbance, not even of the organs of circulation, since it determines the nervous influence mostly upon the lachrymal glands, as disgust does upon the mucous tissue of the stomach, and anger upon the voluntary muscles, while other emotions, like fear, impart to that influence a more universal direction—thus exemplifying, like the physiology of respiration, of the contraction of the sphincter muscles, &c., the manner in which morbific and remedial agents direct the nervous influence upon special parts, acWeeping—continued.

cording to the nature of the former and the natural or acquired susceptibilities of the latter; and connecting the foregoing with the morbific effects of grief and the curative ones of hope and joy, we come to readily understand, through these facts alone, how the nervous influence is variously modified and rendered alterative by physical agents according to the particular virtues of each one—and these coincidences denote the substantive existence and self-acting nature of the Soul. See references under Water, Hot, Index II., and p. 880, \$ 1074.

WHOOPING-COUGH,

treatment of, p. 640, \S 892 $\frac{4}{5}$ h; p. 844, \S 1058 k.

emetics break up a paroxysm by substituting a new modification of reflex nervous influence, since in coughing and vomiting the abdominal muscles are alike concerned, and when an emetic operates it introduces through the reflex nervous action a new combination of movements, and thus necessarily interrupts those upon which coughing depends, and for this reason should the cough, or tickling the fauces, or any other cause bring on vomiting, the paroxysm of coughing will be equally arrested; but in all the cases the results beyond the interruption of the paroxysm will depend more or less upon the special nature of the nauseant or emetic employed-all of which advances our other multitudinous demonstrations of the modus operandi of all morbific and remedial agents beyond the seat of their direct operation through alterative influences of reflex action of the nervous system, and against the crude devices of Chemistry, p. 111, § 233\(\frac{1}{4}\); p. 336-338, § 514 \(\delta\), c. by its direct action upon the main centre of the nervous system it determines the nervous influence in an elective manner, and without regard to intermediate nerves, upon the voluntary muscles, which are thus brought into action by their own inherent properties, to which the nervous influence sustains the relation of a stimulus; and when it is considered with what vehement power the Will may urge the nervous influence upon the muscles of volition, we are supplied with an interpretation of the violence which excessive Joy, Anger, Fear, blows upon the epigastrium, surgical operations, prussic acid, the virus of serpents, &c., may inflict upon the organs of organic life through the same medium, p. 89, § 188; p. 103, § 205; p. Will-continued.

 $\begin{array}{l} 107-111, \ \, \lozenge \ \, 227-233\frac{2}{\pi} \ \, ; \ \, p. \ \, 124, \ \, \lozenge \ \, 243 \, ; \\ p. \ \, 295, \ \, \lozenge \ \, 476\frac{1}{\pi} \ \, ; \ \, p. \ \, 296, \ \, \lozenge \ \, 476\ \, c; \ \, p, \\ 298, \ \, \lozenge \ \, 476\frac{1}{\pi} \ \, h; \ \, p. \ \, 300, \ \, \lozenge \ \, 479; \ \, p. \ \, 302, \\ \lozenge \ \, 481\ \, b; \ \, p. \ \, 319, \ \, \lozenge \ \, 494\ \, b-e; \ \, p. \ \, 323-328, \ \, \lozenge \ \, 500\ \, c-m; \ \, p. \ \, 334, \ \, \lozenge \ \, 509-511; \\ p. \ \, 525, \ \, \lozenge \ \, 828\ \, a-c; \ \, p. \ \, 643, \ \, \lozenge \ \, 893\ \, a. \end{array}$

with rare exceptions, it so disposes the nervous influence that it terminates without instituting reflex actions, as are apt to arise from Mental Emotions; but a remarkable exception occurs in sleeping in an erect posture, especially in roosting, and very analogous to that are the spasmodic affections (particularly of the muscles of the lower extremities when rendered susceptible by diseases of the abdominal organs) which arise from extending or "stretching" the limbs when in a horizontal posture, and as often experienced by the Author, p. 890–891, § 1077. Also, Roosting, Index II.

while the Will limits the nervous influence to whatever voluntary muscles it chooses, the Mental Emotions generally affect particular parts in their natural state according to the particular nature of each one, or as they may be compounded, as Shame the capillaries of the face, Grief the lachrymal glands and stomach, Disgust the stomach mostly, Fear the kidneys, skin, and heart, Anger the voluntary muscles, &c.; and what is thus true of mental emotions is more or less so of certain morbific and remedial agents of a physical nature, as Cantharides strikes at the genito-urinary organs, Narcotics, the brain, Mercury at the salivary glands, &c.; but in a general sense morbific agents are less circumscribed, and some of them, as the predisposing causes of fever, render the nervous influence universally alterative, and coming to conditions of disease this complexion is changed, and all external things, food, exercise, mental emotions, &c., present new phenomena, not only according to their nature, force, &c., but in parts upon which they may have no apparent effect in their natural states, and since the foregoing general limitation of the effects of morbific and remedial agents to particular parts according to the nature of the agent, and the part, and the varying susceptibilities, is entirely opposed to the diffusive action of galvanism and electricity, and as there is no analogy between the exciting causes and modifying influences of the nervous agent and those of which Chemistry takes any cognizance, and

Will-continued.

since the same limitation of effects applies in health with the precision of laws to the Will and Mental Emotions, and as the Will has the nervous medium through which physical agents produce their effects under its own self-acting control in its office of voluntary motion, and as some of the Mental Emotions rarely institute reflex actions, but are restricted to one half of the supposed galvanic circuit, and as the Will nearly always operates exclusively through the motor half,* the proof becomes conclusive that our Chemical friends must look for some other instrumentality than galvanism or any of their known agencies or laws to expound the problems of life and disease. See foregoing references; CAUSES, MORBIFIC: REMEDIES, MENTAL EMOTIONS, the individual Passions, REMEDIAL ACTION, REFLEX ACTION, STRUCTURE, Index II. employed in demonstrating the substantive existence and self-acting nature of the Soul and Instinctive Principle, p. 874-879, § 1071-1075.

INSTITUTES OF MEDICINE.

NOTES.

As stated in the Preface to the Seventh Edition of this work, the Author has affixed some brief Foot-notes to that Edition (as at p. 172, 350, 593, 679, 725, 863, 895, 920); but soon after the first impression was struck off he concluded to introduce a few other Notes at the end of Index II., which will be attached to the copies of that impression which may remain on hand. This method of adding or modifying will be continued hereafter, and references to the Notes thus appended will be inserted in the text in future impressions, and probably, also, other foot-notes, and other improvements. Such, indeed, have been made in this second impression of the seventh edition, as at p. 493, 606, 699, 1052, &c.—September, 1862.

NOTE A.—EXCITING CAUSE OF PARTURITION.

Note A.—In section 8923 d occur some remarks about the institution of labor, and I am now led to other comments by certain suggestions made by Professor G. S. Bedford, M.D., upon the same subject in his late work upon the "Principles and Practice of Obstetrics," and which was reviewed by myself in the "Boston Medical and Surgical Journal," November 7th, 1861. In that Review I remarked that Dr. Bedford, after a general examination of the principal hypotheses relative to "the determining cause of labor, or that peculiar influence which first excites the muscular fibres of the uterus to contraction," and having considered particularly the ovarian hypothesis of Dr. Tyler Smith, and the orificial irritation of Dr. John Power, both of which are founded upon the laws of reflex nervous action, delivers his own rationale in considerable detail. Our Author's doctrine is predicated of the principle that "there seems to be a necessary connection between the first spontaneous movements in the muscular walls of the uterus and a matured development of the muscular structure of the organ itself." That the institution of labor is due to a cause that operates at uniform times not only in the human species but in all animals is sufficiently obvious. It must be independent, in a constitutional sense, of all accidents that may affect the specific periods. The hypothesis of orificial irritation is contradicted not only by the periodical uniformity of the process, which is very variable in different species of animals, but by the variety of presentations, and that woman alone is liable to the imputed cause before the contractile movements shall have begun. We must therefore look to the uterus itself for the requisite provision, and this can be found only in a law which is exactly obedient to a matured development of the organ. But this does not expound the great and wonderful problem—the how or the why the "spontaneous movement" grows out of the "matured development of the muscular structure." Are there any analogies, any physiological principle, to sustain Dr. Bedford's conclusion that there is an inherent ability in the fully developed uterine muscular structure to institute the parturient process independently of any other existing cause, and above all that, as our Author affirms, "it has no connection whatever with a reflex or nervous force"? For this conclusion our Author offers a supposed analogy in the peristaltic movements of the intestine, founded upon the assumption that those actions are independent of the nervous influence, which, however, has not been rendered even probable. Experiments have only shown that other causes are capable of exciting those movements, such as atmospheric air, mechanical injuries, electricity, etc. (§ 262-265, 4751). In the natural condition of the intestine there must be equally an exciting cause of the peristaltic movements as of the action of the heart (§ 47512), or of the respiratory muscles (§ 500 i-m), or of the iris (§ 514 k, 1072 a), or of the sphineters (§ 514 f, g), and, as in the latter cases, what else than the nervous influence in that of the intestine?

And is not this confirmed by the effects of catharties and suppositories ($\S 514 f$)? Why are the natural movements suspended in jaundice, or when food is long withheld, unless bile and the ingesta be remote causes of those movements, and how else can they reach the intestinal muscular tissue than through reflected action from the nervous centres? How else can the stimulus of the blood affect the muscular substance of the heart than through the circuitous route of the nervous system, or what other important function do the cardiac nerves subserve? (p. 303, Ex. 15; p. 321). Physiologists are also greatly in error in supposing that the nervous influence

ceases to operate immediately after apparent death, and therefore in the inference that the expulsive movements of the uterus after apparent death are not excited by the stimulus of the nervous influence. The expulsive efforts are ample proof that there is still remaining life; and various recorded facts substantiate the continued action of the nervous system as long as muscular irritability and contractility remain

(§ 447 d, 637, 1042, 1072 a, Note AA, p. 1131).

As to the experiment of destroying the lower portion of the spinal cord for the purpose of showing that labor may take place without the stimulus of the nervous influence, it has been completely neglected that the uterus is still connected with the essential parts of the nervous system by contributions from the sympathetic nervo and from other parts of the cerebro-spinal system (§ 459 f, 478 b, 483 c, 490). Moreover, it is now well ascertained that the ganglia of the sympathetic nerve, even the plexuses of that nerve, are, as one of their uses, centres for reflected nervous action, especially when preternatural influences are in operation, as when, for example, vesicants subdue deep-seated inflammations (§ 516 d-522, 893). In the case of the parturient efforts after the destruction of the lower portion of the spinal cord, that very injury calls into operation other resources in the nervous system with which the uterus is indirectly supplied. It is also universally conceded that, in the language of our Author, "as a general rule, labor is in part accomplished through reflex nervous action," and it is therefore farther inferable that when labor takes place after destroying the inferior portion of the spinal cord "the general rule" still obtains, and that the experiment supplies no evidence that "childbirth is not necessarily dependent upon nervous agency." The supposed "inherent action" is, possibly, sufficient, per se, for a single contractile movement, but an exciting cause independent of the matured development of the uterus" is necessary to a long series of alternate contractions and relaxations. That condition resulting from the "matured development of the muscular structure of the organ" becomes the exciting cause of reflex nervous actions, just as the want of atmospheric air in the lungs is the remote cause of the reflected nervous influence that determines the respiratory movements-excepting in the case of the uterus the compounded sensitive and excito-motory nerves, which are the channels of the transmitted influences, appertain exclusively to the muscular tissue of the organ. This, however, has its exact analogy in the reflex nervous actions upon which, as I have shown, roosting and sleeping in an erect posture depend, as also the spasms which are sometimes excited in irritable muscles of the lower extremities by a forcible act of the Will (§ 500 dd, 514, p. 891, § 1077). In the former case there is a natural adaptation of the muscles to that exercise of the Will, which, by placing them in a rigid state, establishes a reflex nervous action that maintains them in permanent contraction as in the more compounded case of the sphincter muscles. The same natural provision becomes developed in the gravid uterus to subserve the exigencies of parturition, and is allied to that irritable state of the voluntary muscles in which the Will may institute spasmodic movements. As soon, however, as "the determining cause" has initiated the process of labor, the point of departure for the reflected stimulus of the nervous power becomes compounded, and the fœtus participates as an exciting cause of the reflected nervous influence by its pressure upon the uterus. In this respect there exists an analogy in the first of the respiratory movements as related to all the subsequent, so far as the first in the series is determined by the contact of cold air or other physical causes acting upon the surface of the body, while in all the subsequent movements the point of departure for the reflected nervous influence is the mucous tissue of the lungs.

As to the alternate contractions and relaxations that are maintained by air, mechanical injuries, electricity, &c., in the extirpated intestine and heart, and where there may be no reflected nervous influence determined by those causes through local centres of the sympathetic nerve, such alternations of action are as readily produced by the artificial irritants as by the stimulus of the nervous power in virtue of the natural constitution of those organic muscles, which are specifically designed for that mode of action (§ 262-265, 4751 and references there, 4761 c, 490, 498 e, 500 c-e, o, 514 f, 516 d 8 and 9, 891, 8923, 1077).

NOTE B.—POISONS AND THE ORGANIC NERVE.

Note B.—Some late Experiments by Peliko and Dybrowski, showing the action of certain poisons upon the heart, exemplify the transmission of influences through the sympathetic nerve in the absence of the brain, as set forth in § 461½, 477-478, 481 Exp. 14, 15, 483 c, 484 b, 487 f, g, 488½, 490, 494 Exp., p. 675, § 904 b. They are introduced here, therefore, not on account of their supposed novelty, but as new contributions in support of the doctrines which I have advanced as to the modus operandi of morbific and remedial agents through reflected influences of the nerrous system, and as showing that these influences may be fully propagated through the sympathetic nerve, as is also seen of the natural stimuli in the anencephali (§ 461½ a).

According to a communication made to the Parisian Academy of Sciences by the foregoing Physiologists, poisons derived from the upas antiar, tanghinia venenifera, veratrum viride, digitalis purpurea, introduced into the stomach or inserted in the skin of frogs, arrested the action of the heart in periods varying from ten to twenty minutes, leaving the animal for some time with the exercise of voluntary motion. They found this paralyzing influence to be equally the same when the brain was separated from its connections with the spinal cord, from which they deduce the conclusion that the poisons exert a peculiar effect upon the nerves supplying the heart or such as may influence the movements of the organ. By consulting the references to the Institutes as suggested in this Note, it will be evident from similar experiments long since made (by Brodie, for example, with tobacco, p. 675, § 904 b), that the heart was not paralyzed in the foregoing cases through an absorption of the poisons, but by pernicious influences reflected by central parts of the nervous system.

The experiments possess, also, the interest of showing the difference in functions between the cerebro-spinal and ganglionic systems, and the transmission of influences in organic life (as in the case of the Will in animal life), through special organic nerves, according to the nature of the remote causes and the natural or acquired susceptibility of organs (§ 137-152, 233\frac{3}{4}, 500 \(g-m_4 \), and Note at p. 864).

NOTE C .- ORIGIN OF DEATH.

Note C.—Refers to section 632, page 401. Nothing upon the subject of death can be predicated of man as deduced analogically from the original constitution of animals. The weapons of destruction with which the latter are provided is a cogent proof that death was their primitive allotment, and a still greater may be seen in the universal means of subsistence among the aquatic tribes and the carnivorous of every denomination. The last reaches to man, for whose uses the animal as well as the vegetable kingdom was created, and in which respect the pronunciation of Scripture corresponds with the constitution of man, which is obviously designed for both animal and vegetable food. Man is not only thus isolated, and all reasoning from analogy predicated of the death of animals excluded, but since, also, animals were rendered subservient to mankind as a means of sustenance, and as the death of man is not tributary to any useful purpose whatever in the economy of nature beyond the mere elementary principle, it is evident that death has been ingrafted upon man's constitution without any apparent final cause. This conclusion, though wanting in absolute proof, is prompted by reason in its logical methods of investigation, and it seizes upon Revelation as supplying a remarkable concurrent testimony of the accuracy of its own ratiocination, and as affording a satisfactory solution of the wonderful problem. But that is not all. Man is still more estranged from the brute creation by his endowment, according to my induction from final causes (p. 893), with an imperishable Soul, while the instinctive principle of animals dies with the material body. The analogy, therefore, which has been carried from the mortality of animals to the human race is again rendered nugatory by the final causes of the Soul and of the principle of Instinct (p. 842, § 1078).—Note Pr p. 1142.

NOTE D.—REFLEX NERVOUS ACTION.

Note D .- The demonstrable manner in which light produces sneezing, or the mind in dwelling upon the paroxysm, as set forth in § 514 k-l, 1077, and in which disgust, whether arising from offensive sights or offensive odors, or from a recollection of their effects, gives rise to vomiting, as expounded in § 500 i-m, 503-512, 514, 8923, 1074, 1077, and as an attendant result to sweating (ibid.), and where in the latter case the nervous influence is conspicuously manifested as well in the organs of organic as of animal life, enables us to readily comprehend the involved processes of reflex nervous actions that may be instituted by remedies administered by the stomach or applied to the skin, as variously set forth in this work (§ 228 b, 514 h, 657, 674 d, 692 a, 715, 811, 848, 863, 889 a, n, 902 g, 904 bb, and Index II., Article Skin). Thus, also, it is rendered manifest how agents of special virtues may not only propagate a curative reflex nervous influence directly upon a morbidly susceptible part, as tartarized antimony in the cure of pneumonia, but how, also, the same remedy may simultaneously reflect the nervous influence upon other organs not the seat of disease, as the skin, and thus render that organ the source of a salutary reflex nervous influence upon the morbidly susceptible lungs, as otherwise and variously expounded in the foregoing and other sections.

It may be farther said of sneezing as brought about by the action of light upon the retina, or by the mind in dwelling upon the paroxysm, and of vomiting as occasioned by offensive sights and offensive odors, that in the former case the nervous influence, in being first reflected or directly projected (as the light or the mind may be the remote exciting cause) upon the Schneiderian membrane, acts upon that membrane after the manner of snuff, when the irritation is reverberated upon the nervous centres, the nervous influence again excited and reflected upon the abdominal muscles; while in the case of vomiting, it is the mental emotion alone which excites and projects the nervous influence upon the mucous coat of the stomach (always in a direct manner, according to a distinction which I have made between direct and reflex action, § 227, 500 c-m, 893 a, 896, 903, 1072 a, 1074), where the nervous influence thus determined by the emotion, whether resulting from the spectacle, or the odor, or from the recollection of their effects, acts precisely as an emetic, when the chain of causations ends in the transmission of that nauseating influence to the nervous centres where the nervous power is thus excited in an indirect manner, and then reflected with a convulsive effect upon the same muscles that are engaged in

sneezing.

The foregoing examples are reproduced here that they may be presented in an isolated state, and to attract to them attention both on account of the novelty of the Author's interpretation of the action of the Will upon the voluntary muscles, and of mental emotions upon all parts of the organic mechanism, through the instrumentality of the nervous power, and that they may be recognized as distinct illustrations of the modus operandi of natural, remedial and morbific agents in refutation of the

doctrine of operation by absorption.

NOTE E.—OPERATION OF NARCOTICS.

Note E .- In expounding the therapeutic effects of Narcotics I have endeavoured to show that they operate essentially by reducing irritability and sensibility, and thus render the blood and other exciting causes less stimulating, so that in local conditions of disease attended by an exaltation of those properties the restorative process supervenes upon that sedative influence (§ 891 i, 905 b, 1057). These remarks are intended to illustrate the probable action of Conium and Belladonna in mitigating the severities of cancerous affections, and that the results are in no respect due to an alterative virtue which has been for a long time attributed to those narcotics.

NOTE F.-ALCOHOL versus ANTIPHLOGISTICS.

NOTE F .- To carry out the objects of the Postscript at p. 872 I subjoin the statistics of mortality arising from pneumonia, bronchitis, croup, and consumption in the city of New York during the months of January, February, March, and April of

1861 and 1862, from which it will be seen that the "stimulating plan" of treatment was no more successful than in the same months of 1860.

In 1861 the total number of deaths during the foregoing months was 6987, of which 527 are reported as "Inflammation of the Lungs;" Bronchitis, 185; Croup, 212; Consumption, 1062.

In 1862 the total number of deaths for the same time was 7035, of which are reported as "Inflammation of the Lungs," 498; Bronchitis, 119; Croup, 187;

Consumption, 1165.

The ratio of deaths from pneumonia during the first four months of 1861 and 1862 was about the same as distinguished the corresponding period of 1860, while, had the depletive treatment been adopted, especially bloodletting, which continues to be proscribed in this City of New York, that ratio, instead of amounting to about I in 12 of all the deaths, would not have been 1 in 100. The aggregate mortality, therefore, I reiterate, must not be imputed to any remarkable insalubrity of New

York (p. 760, § 1005 k).—Note Mm p. 1141.

As to the ratio of deaths from Consumption, some improvement may be anticipated from the late work upon that disease by Dr. James Copland, who advocates the antiphlogistic treatment, especially in the early stages. It will, however, be a tardy gain over the stimulating treatment, since it is said, in the leading medical journal of the day, by a rather liberal reviewer of Dr. Copland's work, "that bleeding for hæmoptysis is not a practice which meets with much favour in the present day. Most living physicians with whose opinions we are conversant would as soon think of drawing blood to arrest uterine hemorrhage, or to stop a wounded artery (§ 699 c, 805, 862-864, 890 d-f); and, secondly, that the main improvement (in treatment) depends on the universal acceptation of the doctrine that phthis is essentially a disease of imperfect nutrition and assimilation, and that efforts in treatment must therefore be mainly directed, not to the pulmonary, but to the digestive systems. principal treatment of phthisis nowadays consists in the free administration of nourishing animalized diet, containing a large proportion of the FATTY clements of nutrition; in exercise, with unrestricted exposure to the invigorating influences of sun and air; and in the substitution of a few simple but effective tonic medicines for the effete polypharmacy of our predecessors." The objection to polypharmacy is very well, although it does not apply to any of the most eminent "of our predecessors," whose principal treatment in the early stages of phthisis consisted of bloodletting, a non-stimulating diet, counter-irritants, and free exercise in the open air, but all of which, save the air we breathe, is now so greatly changed that the Reviewer remarks of Dr. Copland's treatment that "we have certainly been surprised to find LOCAL, and in some instances general bloodletting still advised in the first stage of phthisis.' -(The Italics are mine.)-British and Foreign Medico-Chirurgical Review, January, 1862, p. 159.

Now there might seem in the foregoing statistics a sufficient justification of this extended discussion. But it may be said that they are too local, not sufficiently comprehensive, and that as statistics (founded upon the "numerical method") are "the great criterion nowadays of the merits of treatment," they should not be liable to the objection which I have anticipated, although they run through four corresponding months of three consecutive years, and relate to a population of about one million. I shall therefore offer a copious amount of similar testimonials from the same number of the Review to which I am indebted for the foregoing quotations. Thus, in an elaborate Article upon "Military and Naval Hygienics" (the Italics being mine), it is said of "Diseases of the Lungs, &c., including pulmonary consumption," that, "among the troops at home, these maladies occasion more admissions into hospital than all fevers and diseases of the bowels together; and more than three Two thirds of all the mortality in the army of the United times as many deaths. Kingdom are due to them; and of these two thirds, four fifths are due to consumption." "In the Mediterranean garrisons, the proportion of chest diseases to all other causes of sickness has been nearly as high as in Great Britain, viz., a sixth or a seventh of the whole. They have not been quite so fatal; still, the mortality from them alone has constituted between a half and a third of all the deaths. In the North American command, their frequency and fatality have been nearly the same as at

home.

"In the navy, respiratory diseases are the most prolific source of sickness and death." "More than a fifth of the deaths from all causes is occasioned by them." In 1856, out of a total mortality of 629 from disease, 175 deaths were due to pulmonic affections, chiefly phthisis (nearly one fourth); and of the 918 men invalided from disease that year, 103 were discharged on account of consumption, and 49 from

other pulmonic disorders. In 1857, of the total deaths (623) from disease in the service, 129 were caused by consumption" (more than one fifth).—IBID., p. 109, 110.

In reviewing the statistics of consumption, it should not be forgotten that besides the substitution of tonics and stimulants for the "effete polypharmacy of our predecessors," a lavish use of cod's liver oil is a main ground of dependence; though we hold the tonics and stimulants, and the "free administration of nourishing animalized diet," and the absolute neglect of an antiphlogistic treatment, at the early stage of the disease, responsible for the excessive mortality (§ 836, 892 g-i).*

In the MEDICAL AND PHYSIOLOGICAL COMMENTARIES, in an article on the "Pathology of Tubercle and Scrofula" (vol. ii., p. 608-634) and, also, in a critical examination of the "Principal Writings of P. Ch. A. Louis" (ibid., p. 679-815), I have endeavoured, at great length, to substantiate the highly inflammatory nature of phthisis pulmonalis, and have recited the experience of the most illustrious practitioners in behalf of a decided antiphlogistic treatment, especially bloodletting, in the early stages of the malady, and with which my own, throughout a long and active professional life, has fully corresponded. But there has arisen a general, or, rather, a nearly universal acquiescence in Louis' contra-inflammatory doctrine, as deduced by him from the débris of the body, though, as I have unquestionably shown, in opposition to his own dissections (e. g. ut supra, p. 631-633). It is this especially, not the "numerical method," and as generally admitted, which has prompted the stimulating treatment of consumption (§ 756 a). Moreover, in respect to this, and all other diseases, the denunciation of bloodletting is too formidable to be encountered by any but well-established practitioners, and who possess, also, more than Galen's heroic firmness (§ 1004 c, note; also p. 488, § 756 a; p. 722, § 690 q; p. 861, § 1065 c).

NOTE G.—MODUS OPERANDI OF CATHARTICS.

Note G.—The explanation which is rendered in § 889 f of the necessity of profound impressions upon the intestinal mucous membrane by cathartics for successful

* In regard to the causes which have led to an almost universal adoption of a stimulating treatment where the "antiphlogistic" had, with only rare and partial exceptions, obtained throughout the past (\$1004 a), I have represented those of a general nature both in this work and the Medical and Physiological Commentaries (\$487 h, 569 b-c, 621 a, 743, 756 a, 755, 815, 800, 861 b, 967, 979, 999, 999 c, 1001, 1005-1007, 1022-1026, 1063 a, b). But there are many incidental causes, which have given a great impulse to the revolution, and a knowledge of which will be interesting to the future historian. Among the thousand influences of this nature, which are of themselves of important and comprehensive import, may be mentioned the following recommendation, signed by nine of the principal physicians of the City of New York (six of whom, at least, are Professors in some of our Metropolitan Colleges), and which, of course, has been extensively circulated as an advertisement. Thus:

" New York, May 1, 1861.

"Mr. Wm. T. Cutter, Jr., Louisville, Ky.

"Deae Sie,—The great difficulty experienced in procuring Brandy sufficiently pure for medicinal purposes, has induced many of the physicians of this vicinity to adopt Bourbon Whisky as a substitute, both in the hospitals and private practice; and since the latter HAS COME INTO SUCH GENERAL USE, we have reason to believe that a great deal now sold is of very inferior quality.

"Presuming that your residence in the vicinity of the manufacturers of Whisky in Kentucky, as well as your skill as a chemist, will enable you to select a reliable article, and having full confidence in your integrity, we are led to inquire whether you will not aid us in having this market supplied.

through an agency, with the best quality of Pure Old Eourbon Whisky for the use of the sick.\(^1\)
The capitals are mine.

Another favourite stimulant, known as Wolfe's Schiedam Schnapps (or, more familiarly, Holland Gin), is worthy of notice on account of its special recommendation by high medical authority. This gin has enjoyed a distinguished professional patronage and a brilliant career for many years, and the appetite for it has been very recently sharpened by a fresh recommendation signed by seven of the principal physicians of the city of New York, several of whom are Professors in our Medical Colleges. It appears as a newspaper advertisement, and the following extract will show that I do not magnify the extent of the evil:

"New York, March 13, 1862.

"Uddleho Wolfe, Esq.
"Dear Sir.—We have tested the several articles imported and sold by you, including your Gin, which you sell under the name of Aromatic Schiedam Schaapps, which we consider justly entitled to the high reputation it has acquired in this country; and, from your long experience as a foreign importer, your bottled Wines and Liquors should meet with the same demand.
"We would recommend you to appoint some of the respectable apothecaries, in different parts of the city, as agents for the sale of your Brandies and Wines, where the profession can obtain the same when needed for medicinal purposes. Wishing you success in your new enterprise, we remain your

when needed for medicinal purposes.
obedient servants."

All this may seem to be hardly worthy of record, even in a Note; but it forms no small part of the history of the most remarkable revolution that has ever befallen practical medicine, and, moreover, the hope may be entertained that something may be thus contributed toward arresting the career of this wide-spread calamity. It also supplies a principal ground of solution for the disappearance of those remarkable efforts that had pervaded the United States for the suppression of intemperance.

thvasions upon certain obstinate conditions of disease not only plainly refutes the humoral interpretations of the modus operandi of cathartics in their peristaltic action and their effects upon disease, but it lays open the philosophy of the effects of elaterium and of other violent cathartics in sometimes subduing dropsical affections as set forth at p. 655-656, § 893 n, and which is there shown to have been explained "upon the principle of counter-irritation, or metastasis of the physical school," while, at the same time, a confirmation is thus obtained of the inflammatory nature of dropsical effusions, whether acute or chronic, as set forth among other facts in the Author's Medical and Physiological Commentaries, vol. i., p. 180-183, 186, vol. ii., p. 556, note; 1840. Also Institutes, § 892½ k, 892½ b, e, g.

NOTE H.—NARCOTICS versus ANTIPHLOGISTICS.

Note H.-I have occasionally embraced opportunities of contrasting the substitutes for bloodletting in the treatment of inflammations and fevers which have been commended by those who are opposed to the latter remedy (§ 954 b, 960 a, b, 1005, 1006 f, 1068), and although the abstraction of blood is now very generally sacrificed to the ad captandum practice of tonics and stimulants, and all but animal nutriment is mostly proscribed, there has sprung up a narcotizing school whose excesses far surpass any former records of this kind of antiphlogistic treatment, and presents a doubtful alternative for the "tonic and stimulating plan." It seems to be proper, therefore, that these Institutes should be "posted up" upon the peculiar claims of the "opium treatment," and as these consist in effecting narcotization, my purpose will be sufficiently accomplished by showing how it is done-for the method is far in advance of the practice as it existed when the record was made in § 891 c. A greater importance has been also given to the subject by the accessions which have been made to the school from the influential ranks, and that this may be at once apparent, I shall have fulfilled the object of this note by presenting the following quotation from a writer of good repute, who has also quoted the statement from one of the most indulgent Commentators. The particular disease in the present instance was puerperal fever, but the same narcotizing treatment is applied to the common form of peritoneal enteritis. But, in the mean time, the inquisitive reader should refresh himself of the past by turning to § 1005. The first sentence of our quotation is from the text of Professor G. S. Bedford's late work on Obstetrics (1861), and the residue is embraced in an associated note. Thus:

"Professor Alonzo Clark, of the College of Physicians and Surgeons of this city, has employed opium in heroic doses during the prevalence of puerperal fever at the Bellevue Hospital, and with good success. Some interesting details furnished by Professor Keating, the able annotator of Dr. Ramsbotham, touching Dr. Clark's experience with opium in puerperal fever, will be found in Ramsbotham's System of Obstetrics, p. 534. I may here, however, be permitted to quote the following as an evidence of the extraordinary extent to which opium may be administered without fatal results. Professor Clark says: 'Regarding the tolerance of opiates in some of these cases—at the risk of being charged with rashness and trifling with human life —I will make some extracts from case seven. The treatment was commenced at 10 A.M., on the 26th of December, two grains of opium hourly. At 2 P.M., no change in the symptoms, dose increased to gr. iv.; at 3, gr. iv.; at 4, gr. v.; at 5, gr. v.; at 6, gr. viii.; at 8, gr. x.; at 9, gr. xij.; at 11, sol. morph_sulph. (16 gr. to f. 3i.) 3iss.; at 12, 3i.; at 1½ A.M. (respiration 6), 0; at 6 A.M. (respiration 12), opium gr. xij.; at 10, sol. 3i.; at 12 M., opium gr. xij.; at 1½ P.M., sol. 3ij.; at 2½, 3ij.; at 3½, opium gr. xxiv.; at 5, gr. xij.; at 6½, sol. 3ijss.; at 7½, 3ij.; at 9, opium gr. xiv.; at 10, gr. xvj.; at 11, gr. xviij.; 28th, at 1 A.M., sol. 3ijss.; at 2, 3iv.; at 3½, opium gr. xx.; at 4, sol. zijss.; at 5, ziii.; at 6, zijss.; at 6½, opium gr. x.; at 7, sol. zijss.; at 8, opium gr. xxij.; at 1½, sol. ziv.; at 10, ziij.; at 11½, ziij.; at 12, 0. Thus this woman took, in the first 26 hours of her treatment, opium lxviij. and sulph. morph. gr. vij.; or counting one grain of sulph. morph. as four grains of opium, one hundred and six (106) grains of opium. In the second 24 hours, she took opium gr. exlviii., and sulph. morph. lxxxj., or opium four hundred and seventy-two (472) grains! On the third day, she took 236 grains; on the fourth, 120 grains; on the fifth, 54 grains; on the sixth, 22 grains; on the seventh, 8 grains; after which the treatment was wholly suspended. This woman was not addieted to drinking, and, after her recovery, she assured me repeatedly that she did not know opium by sight, and had never taken it, or any of its preparations, unless

it had been prescribed by a physician. This is, perhaps, 'horrible dosing,' and only justifiable as an experiment on a desperate disease; yet this woman is alive to tell her own story, as are several others, who took surprising quantities of this drug. But later observations have shown that the tenth to the thirtieth part of this maxi-

mum is sufficient in controlling the disease'" (§ 960 a, 1064, 1065 d).

Although we may not hope to defeat the attempts to substitute other means for bloodletting, ranging from dry-cupping to tonics and stimulants, or consisting of the most violent poisons of the Materia Medica—aconite, tobacco, veratrum viride, opium, &c. (§ 960, 1065~a)—and where the abstraction of blood may be most demanded by the exigencies of disease, we may reasonably insist that the doses shall not be so large as to incur the penalties of the law were they administered by any other than professional hands. It was worthily said by Sigmond to his medical Class, that

"There is no doubt that any indiscretion in the use of violent remedies, any want of caution, may prove fatal; and notwithstanding the occasional escape of persons after the employment of fearful doses, I would impress upon your minds that you are never justified, because a solitary case, here and there, is thrust before your notice of extravagant quantities having been given, to administer, but with the remembrance of the sacredness of human life, any remedy which may have the slightest uncertainty in the intensity of its action. Nor do I think if any untoward event occurred in your practice from a very large dose that an excuse should be pleaded on the score that in some particular case such a quantity had been fearlessly employed, and fortunately no bad effects had resulted" (p. 720, § 960 a).—Sigmond's Lectures in London Lancet, December, 1837, p. 403, 404.

NOTE I.—REMEDIAL ACTION THROUGH THE HEART.

Note I.—In sections 500 m, 694\frac{3}{4}, 826 cc, &c., I have represented the action of the heart when influenced by remedies as resulting generally from either their modifying effects upon disease and a consequent modification of the nervous influence thus reflected upon the heart, or from a simple modification of that influence generated by the direct action of the remedy upon the part to which it may be appliedeither the gastro-intestinal mucous membrane or the skin—while in § 1065 a I have imputed the effect of certain agents, digitalis, colchicum, veratrum viride, in diminishing the frequency of the pulse to a narcotic virtue, and have objected to the therapeutical conclusions which have, in consequence, been predicated of those remedies. The latter are examples which illustrate the difficulties of medicine; for there can be no greater fallacy than the hypothesis that "remedies which lessen the frequency of the pulse are best adapted to inflammatory and febrile diseases." Every thing depends upon the mode in which the heart's action is influenced. To be significant of a salutary effect, whether the modified action consist in a diminished frequency or any other apparently favorable change, the influence must come especially through a salutary impression upon the parts diseased, if the heart have been disturbed by such affections; or, if such disturbance of that organ have not been thus inflicted, the modifying influence of any remedy upon its action, per se, is either useless or injurious, although a salutary effect of the agent upon any morbid process may simultaneously exert a modifying influence upon the heart's action. To be useful, therefore, the blow must be struck, not at the heart, but at those extreme vessels which carry on the morbid process (§ 410, 411, 639, 750, 999 c); and hence our conclusion, as expressed in the text (p. 860), that the substitution of veratrum viride, &c., for the abstraction of blood in the treatment of inflammation has grown out of very mistaken views in pathology and therapeutics. It is true, however, of some other remedies that diminish the frequency of the heart's action by their direct effect upon the gastro-intestinal mucous membrane, as small and frequently repeated doses of tartarized antimony, and jalap in cathartic doses (§ 516 d, No. 6, 904 bb, 1060, 1063 b), that this effect, which is in no respect due to a narcotic virtue, doubtless contributes to the salutary influence which is simultaneously and essentially impressed by the remedy upon the instruments of the morbid process, and which is indispensable to any lasting effect upon the heart's action if that organ have sustained any disturbance as a consequence of the malady (§ 500 m).

NOTE K.—EXCESSIVE MEDICATION BY QUINIA.

Note K .- To illustrate still farther the empirical nature of the practice of administering large doses of quinia in the treatment of intermittent fever (§ 892 d-k), as well as the fallacy of the humoral hypothesis, and to show the probability that such excessive medication must be injurious, as variously set forth in former sections (§ 675, 863 d, 870 aa, 900, 904 d, &c.), I shall introduce here the experience of Mr. Parkin, of England, who, in 1842, visited the South of France, where the intermittent fever was very prevalent and obstinate, and where some of the resident physicians were just beginning the treatment of the fever by the compound of quinia and carbonic acid gas; and it was particularly to witness the effects of this compound that the visit was made. The dose of the solution of sulphate of quinia along with the gas that was employed by Mr. Parkin was generally an ounce and a half, which contained much less than a grain of the sulphate of quinia. The largest doses had only a grain and a half. His success was so remarkably great that in the following autumn he went to Madrid for the same purpose, where the Minister of the Interior assigned to him a ward in the General Hospital of that Capital to carry on his experiments, and here he was equally successful with the moderate treatment as he had been in the South of France. But it was not only by small doses of the alkaloid that he accomplished his cures, but often by a single dose. And now observe how his critical experience as to the most useful time for administering the dose contradicts the humoral hypothesis, both as to the pathology of the disease and the modus operandi of the remedy, and establishes my interpretation of the latter through reflected actions of the nervous system. "The result of these trials," says Mr. Parkin, "confirm me in a conclusion I had previously formed as to the proper time for the administration of the remedy, which I found to be immediately before the accession of a paroxysm. When thus administered, I have generally found that it shortened the paroxysm, and that it arrested it altogether, upon the average, at the third administration of the remedy. The same result was experienced in old as in recent cases, even where the disease had existed twelve months. There were numerous cases in which no return was experienced after the first administration of the remedy, while in some cases the expected attack was not experienced at all."*—London LANCET, April 29, 1843, p. 139.

That the remedy should be administered at some period of the intermission, and suspended during a paroxysm, has been always regarded as an indispensable rule of practice (§ 675); but in the case of the particular compound now before us, it was found by a critical observer that the most appropriate time was circumscribed within a few minutes. Now, if the doctrine of operation by absorption had any foundation—whether the remedy be supposed to neutralize or extinguish some poison assumed to exist in the blood, according to a large school, or to unite chemically with the solids, according to Liebig and his followers (p. 171, No. 42),—the remedy if administered during the hot stage of a paroxysm of intermittent fever should not as uniformly aggravate and prolong the disease as it arrests its career when administered during the period of intermission (§ 675), and least of all should it be most salu-

tary if given at the precise moment indicated by Mr. Parkin. †

I have illustrated the influence of vital habit by a reference to the periodical return of an intermittent fever through a series of years, notwithstanding the early removal of the subject from a miasmatic region to a climate entirely exempt from intermittents (§ 560); a fact which, in itself, disposes of the whole question before us, whether it respect the assumed absorption of a poison, its continued presence in the system, or the humoral interpretation of the modus operandi of the remedy. Analogous facts abound in the history of diseases, and are worthy the consideration of those who aspire at the realities of Nature, and would escape the seductive simplicity of the substitutions of art (§ 506, 526 c, 657 a, 826 b, 828 a). Again, also, in all our reasoning upon these leading principles in the philosophy of medicine, we should not neglect, in connection with the foregoing subject, the minuteness of the quantity of quinine that may be sufficient to arrest a very violent and protracted fever (§ 870 aa); and the same may be alleged of the arsenical preparations.

^{*} The following is the formula employed: R Sulphate of quinia, grs. xvi.; tartaric acid, grs. lx.; bicarbonate of soda, grs. lxxv.; water, ibij. The alkaline carbonate is added last.

[†] See corresponding evidence and philosophy of the subject at p. 430-432, § 675; p. 548-549, § 863 d; p. 597, § 892 e · p. 739, § 987

NOTE L.—MODUS OPERANDI OF ARSENIC AND ANTI-PERIODICS.

Note L.—As to the modus operandi of arsenic (§ 892 \ddagger g), it is readily seen from the mineral nature of the substance that it cannot exert the same effects as the vegetable substance Peruvian bark, no more so than does the animal product, spider's web, in doing the same thing, exercise the influences of either, no more so than when an emetic, or a strong mental emotion, or loss of blood, suddenly breaks up the same condition of disease. And yet the chemist has the singular infelicity to tell us that all this medley of things cures intermittents equally either by their chemical union with some imaginary poison in the blood, or by forming new compounds with the solids; which is equivalent to saying that arsenic and cinchona and spider's web (neglecting emetics and mental emotions and loss of blood) will as readily unite with each other as acids do with alkalies (§ 675, 863 d, 870 aa, 892 b–k, 900, 904 d, 986).

The vital solidist, in rejecting the chemical rationale, may briefly reiterate the philosophy which he would substitute—that each agent has its peculiar virtues, exceedingly unlike where they are most curative (as cinchona, arsenic, and spider's web), and each exerts its own peculiar changes in the morbid states, places them in other conditions less intensely morbid, and thus enables the physiological laws to institute the restorative process (§ 854, 900, 902 h, 904 bb). No matter, therefore, whether arsenic be administered in simple intermitting fever, or as that disease may be complicated with chronic cutaneous eruptions, when the impression is made which enables the great recuperative law to throw off the fever, the same artificial change may equally induce, through the same constitutional principle, the disappearance of

the chronic affections of the skin (§ 902, 1059).—Note R p. 1123.

Again, that the constitutional effects of arsenic depend upon its primary action upon the alimentary mucous tissue and the subsequent development and reflection of an alterative nervous influence may be distinctly shown by the remarkable contrast in the phenomena and pathological conditions that are induced in different individuals by poisonous doses. It is well known that the symptoms are generally those of violent gastro-enteritis, but that there are rare instances in which the symptoms are such as are produced by poisoning with opium. Of these exceptions, which form a most imposing contrast with the more numerous class of cases, there has occurred in my practice one strongly marked example, in which vomiting was effected with difficulty by emetics, and which would have been mistaken for poisoning by opium had not the nature of the cause been known from the beginning. About an ounce of the white oxide of arsenic had been swallowed, and large quantities of it were thrown off from the stomach. Death took place in about twelve hours. Lethargy came on early, and was very overpowering. No gastric uneasiness or purging. Respiration became very slow some six hours before death, accompanied by a very irregular pulse, varying from twenty to fifty beats in two successive minutes, but not intermitting. The action of the heart was strongly affected by the respiratory movements, which were without any uniformity. They would be suspended for several seconds, and then would follow a long and deep inspiration; and of these movements there were from three to six in a minute. During the suspension the pulse would sink down to its lowest frequency, and when inspiration took place the pulse would suddenly bound from 20 to 40 or 50 strokes, and become much increased in volume. The case being obvious, the distress of the family rendered it inexpedient to request an examination after death. But post mortem examinations have been made in other analogous cases.

The principal remaining point to be observed in the two series of cases is the correspondence of the cadaverous appearances with the phenomena during the action of the poison, and it shows that the difference in the local and constitutional symptoms, in the opposite cases, is owing to the different modes in which the gastro-intestinal mucous membrane is affected by the poison; since it exhibits in one series of cases the most positive signs of inflammation, while in the other, or form of narcotic poisoning, no morbid condition of the stomach at all resembling inflammation is ap-

parent on dissection (§ 512, 826 cc, 841, 902, 904 bb).

NOTE M.-MODUS OPERANDI OF ANÆSTHETICS.

NOTE M.—In speaking of the modus operandi of chloroform and sulphuric ether when respired, I adverted to the difference in their effects when employed in that

manner and as administered by the stomach (p. 864, § 1066 b), and intended to imply that such a difference should not obtain if these agents operate through the medium of the circulation. They should not manifest the effects simply of a diffusible stimulant in one case and of an anæsthetic in the other; for, whether absorbed through the mucous tissue of the lungs or of the stomach, or whether the supposed intermixture with the blood take place in the pulmonary air-cells or at the junction of the chyliferous duct with the subclavian vein, there can be no difference as to the impregnation of the blood, which is the essential fact in question. But a ready explanation of the difference in effects will be found in the vast difference between the vital constitution and functions of the mucous membranes of the stomach and of the lungs, and in the well-known diversity of effects that arise from a thousand causos as they may be introduced into one organ or the other (§ 133-137). Each cause exerts special but different effects upon the mucous membrane of either organ respectively; and according to those effects the nervous influence will be developed and modified in a corresponding manner, and, by its reflection upon other parts, will exert upon them effects corresponding with the primary impressions, as variously expounded in this work.

Again, if it be true, according to Lallemand, that "ether, chloroform, and amylene are absorbed and act first in a direct manner on the brain and other nervous centres, where they accumulate, and are, as it were, stored up, and that, secondly, they afterward proceed to act upon the blood," there should not be, under such circumstances, any necessity for the uninterrupted respiration of anæsthetics to maintain insensibility, nor any sudden subsidence of the anæsthetic influence. But the facts establish an evanescent effect conformable to superficial impressions of a very transitory nature, which as suddenly and transiently rouse the nervous influence, while they equally and as plainly contradict the hypothesis of "accumulation and storing up" (§ 827). Finally, the volatility of these agents is against the doctrine.

NOTE N.—DIGESTION NECESSARY TO NUTRITION.

Note N.—If it be admitted that alcohol, sugar, animal broths, &c., enter the circulation unchanged, it is impossible that they should be tributary to nutrition, since that unique, homogeneous substance the blood can alone fulfil this great ultimate object of the elaborate system of organs which is designed for the formation and vitalization of that fluid, and towards which the first and indispensable step is a positive change instituted in all nutritive matter by the gastric juice, while the kidneys are placed at the other extremity of the series in part for the removal of any matter which may have escaped the organizing influence of the chylopoietic organs. Hence, the application of butter, &c., to the skin, and that most plausible of all devices to sustain the body, enemas of animal broths, must be regarded as fallacious (p. 171, 172, § 350, Nos. 41, 42, 43, 94; p. 222, § 409 b; 440 bb, 441 c; p. 790, § 1032 b).

NOTE O.—CEREBRAL CIRCULATION.

Note O.—In confirmation of the conclusion from my experiments upon the brain that the quantity of blood circulating within the organ has been much overrated, it should have been said in the text at page 826 that both carotids have been successfully tied in the human subject, at an interval of a few days for each carotid, without injury to the cerebral functions. In some animals, as the rabbit, the same operation has been performed simultaneously upon both carotids and one vertebral artery without injury to the brain.

NOTE P.—EXAGGERATIONS OF INSTINCT.

NOTE P.—If the following statement has not been made as an illustration, merely, of the propensity to magnify the endowments of Instinct, it was designed not only to ascribe the rational faculty to animals, but, in presenting a case of dishonesty, to impute to them the moral sense or conscience (§ 1078 h, l). It is derived from Dr. John Brown's veracious Horæ Subsectivæ (vol. ii.):

"Mr. Carruthers, of Inverness, told me a new story of these wise sheep-dogs. A

butcher from Inverness had purchased some sheep at Dingwall, and giving them in charge to his dog, left the road. The dog drove them on till, coming to a toll, the toll-wife stood before the drove demanding her dues. The dog looked at her, and, jumping on her back, crossed his forelegs over her arms. The sheep passed through, and the dog took his place behind them and went on his way."

NOTE Q.—PARAPLEGIA AND REFLEX NERVOUS ACTION.

Note Q.—In expounding the causes of a form of paraplegia which Dr. Brown-Séquard denominates reflex, in his recent "Lectures on Paralysis of the Lower Extremities" (1861), several principles are recognized that are tributary to some of the important doctrines of these Institutes. The Author supposes, for example, that affections of internal organs will not only induce a congestive state of some portion of the spinal cord that will lead in a direct manner to paralysis of the lower extremities, but that at other times they will propagate a morbific influence through sensitive upon excito-motory nerves, and thus occasion "a contracted or spasmodic condition of the blood-vessels of the spinal cord, unaccompanied by actual structural alteration," which results in paralysis of the lower extremities. Although it be true that the supposed contraction of the blood-vessels cannot be anatomically shown, but is inferred from the absence of morbid vascularity in connection with an experiment to be soon mentioned, and although I apprehend that the supposed contracted state of the blood-vessels, if founded in fact, is no more occasioned by reflected nervous influence than the simply congested ones in the other series of cases, and that they are on common ground throughout, in a physiological sense, as sources of paralytic influence, I present the problems not only as admitted exemplifications of the production of spinal disease by morbid states of internal organs, but as introductory to a demonstration by our able physiologist of the local and special influences which are exerted upon the blood-vessels of the spinal cord by irritations of distant organs, particularly the kidneys, through which the vessels may be brought into a state of contraction, and that the cord thus artificially affected may exert a paralyzing effect upon the lower extremities. The following is the demonstration:

"A contraction of the blood-vessels in the pia mater of the spinal cord I have seen taking place under my eyes when a tightened ligature was applied on the hilus of the kidney, irritating the renal nerves, and when a similar operation was performed on the blood-vessels and nerves of the suprarenal capsules. Generally, in these cases the contraction is much more evident on the side of the cord corresponding with the side of the irritated nerves, which fact is in harmony with another and not rare one as regards the kidney, and often seen by me after the extirpation of one kidney, or one suprarenal capsule, that is, a paralysis of the corresponding lower limb."

The novel and interesting fact in the foregoing quotation consists in the influences which were actually seen to have been exerted upon the blood-vessels in the spinal cord by irritations of organs remotely situated, and the corroborating light which is thus reflected upon the philosophy inculcated in these Institutes concerning the transmission of influences to and from the nervous centres, whether brain, spinal cord, or ganglia and plexuses of the sympathetic system, through which I have interpreted not only the diseases which follow consecutively upon each other, but the modus operandi of morbific and remedial agents, and have thus endeavoured to demonstrate the artificial and fictitious nature of the entire fabric of humoralism. Even Brown-Séquard argues from his experiment, especially, that reflex paraplegia is occasioned by "a contracted or spasmodic condition of the blood-vessels of the spinal cord, owing to an irritation reflected upon their walls, and originating from without, unaccompanied by actual structural alteration." Such may or may not be the immediate cause of the paralysis; but that influences upon the vascular system of the brain, and upon the cerebral substance, are constantly exerted by remote affections and by morbific and remedial agents, is corroborated by most of the phenomena that are presented throughout the vast fields of pathology and therapeutics. So obvious is all this, and such are the special developments and modifications of the nervous influence, and such, accordingly, are its effects in organic life, that I have imputed much of the depressing effect of loss of blood to a contraction of the cerebral vessels as contributing to the development of that depressing nervous influence which is so largely concerned in the operation of loss of blood (§ 942, 950, p. 827, § 1056), and, on the other hand, the resistance of its effects to a stimulating nervous influence arising from an excited state of the cerebral blood-vessels in inflammations of the brain and of other organs (§ 233\$, 974, p. 828, § 1056, Donder).—Note T p. 1125, Warren's case. Also, p. 920, Note.

NOTE R.—REMEDIAL ACTION, CHEMICAL DOCTRINE.

Note R.—Chemistry, as we have seen (p. 171, § 350, Nos. 41, 42, &c.), informs us that remedial agents accomplish the removal of disease by uniting either with the solids or the blood, or by neutralizing some poison supposed to be intermixed with or contaminating the blood, or by expelling the poison from the body, &c. Without having called upon Chemistry for the proof of these assumptions, I have shown that they are variously contradicted not only by the whole history of remedial action and the soundest principles in pathology, but by the logical facts of Chemistry itself. Among the multitude of the former nature the consideration alone of the variety of things which will quickly subdue an intermittent fever (cinchona, arsenic, spider's-web, opium, an emetic, blood-letting, mental emotions, &c., § 900, 986-988, Note L), is demonstrative of the fallacy of the entire compass of the chemical rationale. Nevertheless, it is my purpose in this Note to add a few words of comment upon that branch of the doctrine which assumes that remedies unite chemically with the blood or with the solids, and that they thus transmute the morbid into healthy conditions. This is Liebig's philosophy, and obtains extensively in the medical ranks. It has the air of science upon its front; but it is as unmitigated an assumption as the doctrine of the permeation of tissues set forth in § $350 \ge n$, and is contradicted by the realities of Chemistry. Take, as an example, the statements quoted at p. 171, Nos. 41, 42, from Liebig's "Animal Chemistry." What possible apology, derived from the domain of chemistry, can be offered for the proposition that—"if, by the introduction of a substance, certain abnormal conditions are rendered normal, it will be impossible to reject the opinion that this phenomenon depends on a change in the composition of the constituents of the discased organism, a change in which the elements of the remedy take a share in the formation of new or transformation of existing compounds similar to that which the vegetable elements of food have taken in the formation of fat, of membranes, of the saliva, of the seminal fluid, &c."!

The foregoing assumption derives its importance from the general currency which it has obtained in the medical profession. Upon this dictum have been founded the enormous abuses of iron in the treatment of pulmonary consumption, anæmia, chlorosis, &c., and, indeed, the general administration of remedies, whether they consist of elementary substances, like iodine, or of inorganic or organic compounds, some of which (as the phosphate of iron) have obtained the name of "chemical food." Iron, particularly, is supposed to meet, in this way, the exigencies of an endless train of the most dissimilar maladies, on account of its assumed deficiency in the blood and of its uniting readily with the globules. But it is remarkable that it appears not to have been considered that nothing but food, properly so called, undergoes digestion, certainly not inorganic substances, nor the organic of the Materia Medica, and that without antecedent digestion by the chylopoietic organs every thing which gains admittance into the circulating mass of blood must fail of being appropriated to any useful purpose, and must necessarily exist in the same isolated, inanimate state till it is ejected by the emunctories.* If it exert any therapeutical effect it can be only through its direct action upon the solids as a foreign agent (§227 f, 904 c). We have seen that even saccharine matter (p. 788-790, § 1032 b), broth, even (Note N, p. 1121), to be appropriated must be digested, vitalized, subjected at least to the gastric juice before they enter the circulation. Otherwise, they are effete matter. Whether, therefore, regarded as nutriment, or other things as remedial agents in virtue of their "elements taking a share," &c., as quoted above, the doctrine, now in the ascendant, is alike discreditable to medicine and to chemistry (§ 13, 17, 353, 354, 360, 837, 847 a).

And now a few words more particularly as to iron, which, like alcoholic liquors, quinia, and opium, has become a panacca. Strangely enough, this substance, whether in the form of an element, or of its compounds, is supposed by chemists as well as physicians to unite as readily with the blood as oxygen gas, while there is no analogy in the cases, either as it respects the chemical aspect of the subject, or the organs provided, respectively, for their incorporation with the blood-being the peculiarly constituted lungs in the one case (§ 447½ e, 827 b), and a very complex and elaborate system of organs in the other (§ 353, 354). The only possible mode in which iron can become united with the globules of blood is through its connection with organic compounds, duly digested and vitalized by the whole labyrinth of the chylopoietic organs (§ 17, 360), and its presence is limited to the blood alone

^{*} Contrary, therefore, to general belief, water is in no respect appropriated, but merely serves to dilute the blood. See § 271, 419 c, S27 b, 1088 b.

(§ $447\frac{1}{2}$ a, No. 1). Whatever benefit, therefore, iron bestows either upon the blood or the solids can be interpreted only upon the principles of vital solidism,—alone by improving the functions of digestion. Iodine, lime, all the elements of the body, observe precisely the same rule as to their incorporation with the blood or with the solids, while it is just the reverse with plants (§ 11, 14, 17, 360). It is among Liebig's enlightened statements that iron exists in the blood in the state of an "organic compound" (§ $447\frac{1}{2}$ a), and as this is truly its condition it operates as a farther confirmation of the foregoing physiological doctrine.

NOTE S.—TYPHUS AND TYPHOID FEVER.

Note S.—But little is said specifically of typhus fever in these Institutes, and that little occurs mostly in sections 686 b, 892 q; but in the Medical and Physiological Commentaries the subject is discussed extensively, particularly in the articles upon the Medical "Writings of Louis," and upon the "Philosophy of Venous Congestion" (vol. 2). In these Essays the Author has shown that there is no such affection as typhoid fever as distinguished from typhus fever (an opinion, also, of the best informed), and that this disease does not originate on this continent south of the latitude of about 41°. The Author, who became familiar with typhus fever during his pupilage in Boston, and was extensively concerned with it in Montreal during the first five years of his professional life, is enabled to say very confidently that the disease is of rare occurrence in the city of New York and surrounding country, and only so where the predisposition has been contracted in a more northern latitude. Such, too, is the testimony of able and long established physicians in this city, as recorded by the Author in the Essay on the "Philosophy of Venous Congestion" (Commentaries, vol. 2, p. 449–451, note). The following quotation from that work affirms the same of places still farther south:

"The hospital of Philadelphia has furnished many instances of typhoid or typhus fever; but we infer not only from the foregoing facts that they were either imported cases, or derived, as in the sporadic cases of our own hospital, from cellars, &c., but from the long experience of the distinguished Dr. Dewees, of that city, who remarks that he 'has never had an opportunity of seeing a case of typhus, although,' as he says, 'we hear constantly of this disease, and our bills of mortality never fail to record deaths from this fever.'—Dewees' Practice of Physic, p. 170, 171. And so Dr. Davidge, in his edition of Bancroft on Fever, &c. (p. 518), 'Typhus,' he says, 'is not, so far as my observation has extended, a disease of Maryland, perhaps not of America, at any rate not south of the New England States.' 'Typhus,' says Bancroft, 'is properly a disease of cold climates' (ibid, p. 342). John Hunter considered it a disease of winter. 'Heat,' he says, 'proves a prevention to the disease as much as cold forwards its production.'—London Medical Transactions, vol. 3, p. 348. The same statements are made by Blane, Lind, and Trotter, in their respective treatises on Scurvy, &c."—Medical and Physiological Commentaries,

Vol. 2, p. 450.

As to Louis's distinction of "typhoid" from typhus fever, I have shown it, in each of the foregoing Essays, particularly in the analysis of the "Writings of Louis," to be simply a fiction. So far as the celebrated Parisian malady had any affinity to typhus fever it was purely typhus. I shall, therefore, without farther preface, proceed to say—partly in defense of the ground which I have hitherto taken upon the subject, and partly on account of the mortality attendant upon the disease—that the so-called "typhoid" or "typhus fever" that has prevailed as a most fatal epidemic among the hosts of the federal and rebel armies during the last fourteen months (now September, 1862) is the common congestive, bilious remittent fever, but which is made to put on some of the worst symptoms of typhus fever, (such as delirium and subsultus tendinum), by the general treatment of the affection, (with some distinguished exceptions), from the very outset, by tonics and stimulants, of which "Bourbon whisky" (p. 1116, sub-note), and quinia in potential doses (§ 892 d), are prevailing favorites. For the purpose of informing myself as to the diseases of the federal army, from their earliest to their advanced stages (the latter of which now abound in the hospitals of New York), I visited the principal encampments, and was in constant intercourse with the sick during the latter part of July, the whole of August, and the former part of September, 1861, at the large and numerous hospitals in and around Washington, and the regimental hospital tents, and,

also, similar rendezvous of the sick at and about Fortress Monroe. These hospitals and tents were thronged with the subjects of intermittent and remittent fever, but I saw not a case of typhus fever, and recognized in every case of the so-called "typhoid fever" the familiar remittent, the usual companion of the intermittent, generally mild at its invasion, but apt to be soon aggravated and often rendered fatal by the tonic and stimulating treatment. Such was much of my experience with the "Army of the Potomac;" but not so with the fewer troops then at Fortress Monroe and its vicinity, where the antiphlogistic practice mostly obtained; and although the fever was identical with that of the vast army in the region about Washington, the mortality was very slender, and limited to the stimulating practice. Here I saw patients affected with the reputed "typhoid" restored in twenty-four to forty-eight hours by an emetico-cathartic of calomel and ipecacuanha. This was as late as September. The contrast between the two methods was very impressive.

"The regular correspondent" of the New York "Evening Post," in a communication dated Washington, January 10th, 1862, remarks that—"there is here an immense number of cases of the so-called typhoid fever. The peculiarity of this fever, as it is developed in the vicinity of Washington at the present time is, that it is of a malarious type and origin, so that if treated as a malarial fever it soon succumbs, but if treated as an ordinary type of the typhoid fever it is very fatal."

Nor can I refrain from alluding to an experiment which has been extensively made in the army of employing quinia, and "Bourbon whisky" or brandy, as prophylactics. In the Medical and Physiological Commentaries I have inquired into the history of prophylactics, as exemplified particularly in the use of calomel to the extent of salivation, blood-letting, and stimulants, the first two of which have been tried upon an extensive scale, especially upon armics invading the West Indies, when it was found that loss of blood lessened the susceptibility of the system to the causes of the prevailing fever, besides, doubtless, counteracting the stimulating effect of the ardent heat of the climate and of the animal food. In another instance Robert Jackson illustrated the principle under consideration, and set forth triumphantly the medical aspect of temperance, by banishing alcoholic liquors from the British Army (p. 396, § 621 a, 659 b, 692 b, c, 999, 1006 c—1008, 1065 c, 1068 a).—The reverse of all this has attended the stimulants when employed as a protective means, having operated not only as subordinate predisposing causes by rendering the system more susceptible to the action of the miasm or essential predisposing cause, but also as exciting causes (§ 630 e, 787, 801, 810, 813, 815, 961).

NOTE T .- SYMPATHETIC OR REFLEX NERVOUS ACTION.

Note T.—The following instance of reflex nervous action corresponds with the experiment of reducing the temperature of one hand by placing the other in cold water, as related in section 1044 a, and with the well-known sense of itching, &c., that springs up as a sympathetic consequence of a similar sensation in the corresponding part of the opposite side of the body. Thus—"A singular case is noted in the Cairo military hospital (December, 1861), of a man who was shot in the right leg and had it amputated. Sympathetic action took place at once in the other limb, and at precisely the same part where the knife had severed its fellow a similar pain was felt. So severe did this become that the leg is bandaged and treated as if itself wounded."

For the purpose of showing the inherent power of action in the arteries, and how that action is excited and otherwise influenced by the nerves, and how that influence may be exerted through the reflected process, and how, also, the reflex nervous influences are remarkably displayed in corresponding parts of opposite sides of the body, and forming, moreover, a good example of continuous sympathy, I introduced the following case into the Medical and Physiological Commentaries from Warren's "Surgical Observations on Tumors."—Thus—"In a case where Dr. Warren tied the right carotid on account of an erectile arterial tumor situated at the internal angle of the right eye, this vessel and its opposite fellow and their branches pulsated with violence. The ligature on the right carotid removed the pulsation of the left, although 'the vibrations were more conspicuous on the left than on the side originally deranged.' 'The perfect success, from tying the right carotid, showed the affection was altogether sympathetic'" (p. 827, 1056, p. 920, note).—Med. AND Phys. Com., Vol. 2, Article, Theories of Inflammation, p. 149—1840.—See Note Q. This well

known disposition of the corresponding parts of opposite sides of the body to sympathize with each other has its foundation, of course, in an identity of anatomical and physiological constitution, which is very well shown by the following case of purpura-hemorrhagica, occurring in my practice, and recorded in the Essay on the "Philosophy of Venous Congestion," in MED. AND PHYS. COM., Vol. 2, p. 473. The case was introduced there for the purpose of showing the active, inflammatory nature of purpura-hemorrhagica, in opposition to the humoral pathology, and to exemplify the beneficial effects of blood-letting in that affection (§ 1002 d).—Thus the Commentaries—

"The patient having passed a few months on the alluvion of the Mississippi was attacked on his return to New York with an irregular intermittent fever. In its early stage a general extravasation of blood took place over about one half of the posterior part of each humerus, occupying in each arm the central part. The inferior portion of the lobe of each ear was distended with extravasated blood, and just at the middle of each helix was another narrow oblong extravasation of about half an inch. A similar appearance existed in the conjunctiva of each inner can thus of the eye. There was not a trace of any effusion in any other part, or from any of the internal membranes. The parts where it existed were very tender to the touch. There were obvious signs of hepatic congestion. A large abstraction of blood immediately arrested the effusion, and improved at once the strength of the patient, who soon became convalescent. The symmetrical peculiarity of this case is worthy, also, the consideration of the humoral pathologist" (§ 1002 d).

NOTE U.—CONTINUOUS SYMPATHY, OR CONTINUOUS INFLUENCE.

Note U.—Continuous sympathy, unlike reflex nervous actions, does not involve the agency of the nerves excepting as they are an elementary part of the compound tissues; but the impressions resulting from continuous sympathy or continuous influence are constantly giving rise to reflex nervous actions in organic life. This, as already briefly stated, is distinctly seen in the action of suppositories, enemas, leeches applied to the anus or to the septum nasi, croton oil applied to the tongue, &c. (§ 129 c, f, 498, 516, No. 2, 828 d, 923 d). The examples embraced in the foregoing sections are intended to illustrate the subject through impressions made upon the intestinal mucous tissue, and, therefore, there should be associated with expositions of this philosophy the consideration that peristaltic motion, in the natural state of the body, is excited immediately by the action of the nervous influence upon the intestinal muscular tissue (§ 233\frac{4}{3}, 475\frac{1}{2}, 490, 514 f, &c.).

As some important principles in medicine are involved in the foregoing philosophy, whether continuous influence be regarded in its abstract sense, or as instituting reflex actions of the nervous system; and for the sake of having the whole philosophy of the subject before us in this Note, and with reference to what I am about to say of rhubarb, I shall recapitulate, in a few words, some of the expositions already made. Croton oil affords a clear illustration, as it exerts a cathartic effect without entering the stomach, as when applied to the tongue of an apoplectic subject, or when introduced into the rectum in the quantity of a drop. The impression exerted upon those places is propagated continuously along the mucous tissue (§ 498), and this, being equivalent to the direct passage of a cathartic, establishes early an alterative reflex nervous action which falls upon the muscular tissue of the intestine, and thus induces purging, and upon various other parts according to their existing susceptibilities, the activity of the agent, &c. Suppositories and enemas observe the same rule, whether they be stimulating, irritating, sedative, anodyne, soporific, &c., the reflected nervous action being modified according to the nature of the exciting cause (§ 889 a, b, g, 890½ d, 891½ k, 893 a). So, also, of leeching, as expounded in sections 498 f, g.

The foregoing retrospect contemplates among its purposes a confirmation of the philosophy by the action of rhubarb, and a demonstration through that action of the physiological operation of cathartics as distinguished in these Institutes from the doctrine of operation by absorption. It may be very briefly stated. If a little rhubarb be chewed when a cathartic is about taking effect, it will often very sensibly increase the peristaltic movements within a few seconds, and without being swallowed; the mouth itself being a point of departure for the reflected nervous influence. Doubtless the same is true of some other cathartics,

NOTE W.-AMERICAN MEDICAL PROFESSION AND GREAT BRITAIN.

Note W.—Perhaps in consideration of what the Author has said at page 460 of the superiority of the American over the European Medical Profession, it is but fair that the opposite side should be permitted to speak through these Institutes, according to the Author's usage; and this may be done emphatically by an extract from an article lately published by the Author which embraces the opinion of the

leading medical Journal of Europe. Thus-

"It is time that a greater interest should be manifested for our own medical literature—not a whit behind that of Great Britain, which has hitherto contrived to over-ride our own. We have permitted ourselves to be whipped into this ignominious condition-allowing all that may be due to the jealousies of domestic competition; and that there is no relaxation of the systematic discipline from abroad, or of our submission to it, we are assured on turning to the Review of Professor Gross' late 'American Medical Biography,' in the July (1861) number of an American edition of the British and Foreign Medico-Chirurgical Review, in which, after a profusion of ridicule of what it denominates the 'biographers and the biographees,' and a characteristic John Bull hit at 'the Union now in process of disruption,' it is said, as a final and summary conclusion, that, 'We shall be sorry if it is ever our lot again to meet with an American Medical Biography.' This very Journal, too, which never spared what is able in the medical literature of these United States (but only what is ephemeral), notwithstanding its republication and support for near half a century by those whom it maligns, now, taking counsel of the past and encouraged by the hope that 'the Union is in process of disruption,' would not only extinguish our 'dii immortales' and all their contributions to a Nation's best wealth, but the very Nation itself." P.S. The republication, I regret, is discontinued.

NOTE X.-RIGHTS OF AUTHORS.

Note X.—When the Author was speaking, in his reclamation, of the agency of the nervous system in the production and cure of disease, at page 916, and as set forth by himself in his "Essay on the Modus Operandi of Remedies," published in the year 1842, and taught annually from his professorial chair from that day to the present (1862), it would have been, perhaps, more satisfactory to the reader had the Author stated that all that is embraced in the Institutes (first published in 1847), between sections 896 and 905 b, inclusive, and extending from page 662 to 681, is a literal transcript of the "Essay on the Modus Operaudi of Remedies," published in 1842, which, of course, comprehends the Author's philosophy of the operation of counter-irritants as expounded in § 905 a, being the example of the seton.

But, in a reclamation so important and comprehensive as the Author's, it may be still more satisfactory to those who have not a ready access to the "Essay" should the Author recite an example from the "Essay," that it may be compared with the corresponding part of the Institutes. Take, then, as a continuous example, section 902 d to section 902 l, inclusive, of the Institutes, and the Essay from p. 44 to p. 49. Thus the Essay—

"The examples of sympathetic influences, through the reflex action of the brain and spinal cord, are almost endless, as they also are in every part of the animal organism. They supply the most ample ground for the interpretation of the effects of remedial and morbific agents in their wide range of influences. The modifications of the circles of sympathy which relate to the respiratory system alone, as in coughing, crying, laughing, yawning, &c., are a fruitful field of inquiry into great and precise laws, and extensively applicable to the philosophy of medicine. The only difference is, that, when disease is established in a part, or when remedial agents operate, the organic properties of the part are altered in their nature, and, of course, the organic actions over which they preside. A specific impression, in the latter cases, is transmitted to the cerebro-spinal axis, and from thence reflected through other nerves upon the organic properties of other parts, and, according to its nature, disease will be produced or mitigated in those parts. However complex and variable, therefore, the phenomena, nothing can be more simple than the principle through which all these changes are produced,

"When an emetic operates, the philosophy of its influences is the same as that which relates to respiration, &c. The impression upon the stomach is transmitted to the brain and spinal cord through the pneumogastric and ganglionic nerves, the nervous power developed and reflected in the foregoing manner upon the respiratory nerves, while another current descends along other fibres of the pneumogastric to the muscular tissue of the stomach. If the emetic operate, also, as a cathartic, then a new chain of actions is established, in the same way, in the abdominal muscles, while a current of the nervous power is propagated upon the muscular coat of the intestines.

"But, in the foregoing case something more happens than in the natural processes. Here the exciting cause possesses peculiar virtues, is of a morbific nature, and it not only makes peculiar impressions upon the alimentary mucous tissue, according to the exact nature of its virtues, but it modifies the nervous power in a corresponding manner. If the stomach be the seat of disease, the direct impression upon that organ, or the change which an emetic may effect in its vital condition, will be more or less varied from what is exerted in a state of health. It may, therefore, prove curative to the stomach by this direct influence. But the nervous power is also modified according to the impression produced upon the organic properties of the stomach, and is sent abroad, with alterative effect, upon various parts of the system. According to a law by which diseased parts are far more susceptible of influences from vital stimuli than such as are not diseased, the modified nervous power will fall with far greater effect upon the former than the latter. The organic properties and actions of one may be profoundly and permanently affected, while the latter are only moderately and very temporarily influenced. In consequence, also, of the deep effect which the modified nervous power exerts on the diseased parts, they may return, at once, to their natural state.

"But the milder influences which are set up by the nervous power upon parts in health, or in comparative exemption from disease, play, also, their part in the salutary process. If the emetic operate also as a cathartic, impressions are transmitted from the intestinal mucous membrane to the cerebro-spinal system, the nervous power developed and modified according to the nature of these impressions, and radiated abroad as when the result of the action of the emetic upon the stomach, and with effects corresponding to this new development and modification of the

nervous power.

"Again the skin is influenced in the foregoing manner, and this organ transmits that impression to the cerebro-spinal axis, and develops and modifies the nervous power accordingly, when it is, as in the other instance, reflected abroad, and is felt by various parts according to their degrees of susceptibility. Various other circles of sympathy of the same nature set in, and become too complex for analysis; but all may fall with one concurring, curative effect upon the diseased susceptible

organs.

"We thus see that when vomiting springs from the operation of tartarized antimony, and often from ipecacuanha, it is only one of the consequences, and a minor one, of the peculiar irritation of the gastro-mucous membrane. Other and far more powerful influences are determined, simultaneously, upon the organic properties and actions of distant and diseased parts (perhaps as distant as the most remote extremity), by the same nervous power that shook the respiratory organs during the act of vomiting. And often, indeed, does it happen that those influences are propagated with the most profound effect when the act of vomiting fails of being consummated; and nausea alone shall send with prostrating effect the modified nervous power over the whole system; when we shall see it simultaneously bathing the whole surface with perspiration; pouring the saliva from the mouth; breaking down a tumultuous excitement of the heart and arteries; starting on the instant a torrent of bile, and an equal effusion from the intestinal mucous membrane; and at the next moment, calling up a magnificent play of reflex actions for the evacuation of the fluids, after the manner of an active purgative,—these very effusions, also, instituting other circles of sympathy, which join in the great work of curative movements. Should vomiting now follow, then shall you speedily see the vital energies returning,—the cold pale skin giving place to a florid hue and a warm perspiration,—the sunken features starting into the fullness of health, -the gastric suffering gone as a luxury obtained, -the general whirl of anxiety and distress converted into calm tranquillity,—the headache dissipated,—the twang of the croup, or the grunt of pneumonia, no longer sounding an alarm ;-and, all this stupendous succession of events, from the beginning of nausea to the restoration of the vital energies and the near

resolution of disease,—composing a most astonishing consecutive series of reflex actions,—may require less time than I have hastily employed in this general allusion to the subject. And now can it be entertained, that this has been the result of absorption, or that the laws of chemistry or physics have had any connection with

the phenomena?

"The foregoing may be taken as an example of the principle which concerns the modus operandi of all curative or morbific agents, whether physical or moral, and of all the developments of disease that arise as sympathetic consequences of each other. In respect to emetics, however, it should be considered that all do not produce the foregoing effects, and that with the exception of the act of vomiting, the results will depend upon the precise nature of the emetic, or the manner in which it modifies the nervous power and thus impresses the organic properties. This explains the difference in results between tartarized antimony, ipecacuanha, sulphate of zinc, warm water, tickling the fauces, the mechanical irritation of undigested food, the shock of a fall, of a surgical operation, sailing, whirling, offensive

sights, offensive odors, loss of blood, and even their recollection, &c.

"When the alterations, of a sympathetic nature, are more slowly produced, as when mercury induces salivation gradually, and brings the whole system under its influence, or when small, and repeated doses of tartarized antimony overcome inflammations of the lungs, &c., the nervous power is developed and modified at each successive dose, and the repetition of its influence upon the organic properties of diseased parts remote from the stomach establishes progressive changes, till an absolute condition of disease may be induced in certain parts, as when mercury salivates; while the analogous influences which are exerted on parts already diseased supplant the naturally morbid states by others of an artificial nature, from which the organic properties are able to return to their healthy condition. But these impressions must be frequently repeated; for if the interval be long between the administration of the doses of such agents as only produce their effects in a gradual manner, the diseased conditions, not being placed in the way of the recuperative tendency, will throw off the artificial impression, and the original intensity of disease will be thus restored, &c. The permanent operation of the nervous power in particular parts of the animal fabric, as in the sphincters, supplies an elegant parallel with the foregoing uninterrupted influences of the same power as developed by remedial or morbific agents, &c.

"When moral causes operate in the cure, or production of disease, they act directly upon the cerebro-spinal axis, and develop and modify the nervous power according to the nature of each mental affection; and, as in the case of physical agents, the nervous power thus developed and modified may be determined as well upon the organic properties of the brain and spinal cord, as upon other parts. The blow upon the region of the stomach, or the opening of a thecal abscess, which have destroyed life on the instant, operate in the same way as the paroxysms of anger, or of joy, which have been as suddenly fatal. In these cases the nervous power is first determined with a fatal effect upon the organic properties of the nerv-

ous centre."

Again, in the Essay, at p. 51 is the following correspondence with the Institutes at p. 672, § 904 a, which is introduced here on account of the Author's theory of the diverse modifications of the nervous power, and the same doctrine as quoted in

the last paragraph at p. 914 of Institutes. The Essay thus-

"The nervous power is not only variously excited, exalted, or depressed, or modified in its kind, and produces influences upon remote parts according to these changes, but it is reflected upon particular parts according to their existing susceptibilities, the nature of the remote cause, and the part upon which the remote cause may operate. Thus one impression from cold, as a blast of cold air, or a drop of cold water upon the skin, will rouse the respiratory muscles. Another impression from the same cause will excite catarrh, or pneumonia, or articular rheumatism. (See Med. and Phys. Comm. vol. 2, p. 18, 41—50.) Mercurial ointment will determine the nervous power specially upon the salivary glands, and liver, and the same effects arise from the action of mercury upon the stomach. Cantharides, internally or externally applied, irritates the neck of the bladder. One degree of impression by tartarized antimony upon the stomach determines the nervous power upon the respiratory muscles, and vomiting is the consequence; while it simultaneously reflects the same power upon the skin, as it does in smaller doses, and or while the presentation is a Consequence,—and so on. But these examples embrace," &c.—The emphasis of Italics and Capitals does not occur in the Essay.

NOTE Y .- THE NERVOUS POWER AND ELECTRICITY.

Note Y.—Whatever the Author may have said in objection to the supposed identity of the Nervous Power and Galvanism, and especially in his remarks as to the electrical circuit (p. 644, § 893 a, &c.), he desires to be understood as fully recognizing the fact that electrical currents may be developed artificially in nerves, even when detached from the body. This was demonstrated by Du Bois-Reymond, whose method of observation is well and briefly stated in the following extract—

"Every fresh excitable nerve is the source of electric currents, as may be proved by placing the two ends of the wire of a galvanometer in contact with it. But the position of the nerve is of great importance. If the nerve be placed so that the wires touch two points of its surface at an equal distance from the central point (equator) of the nerve, no deviation of the needle takes place; but when the wires are placed so that one touches the transverse section of the nerve, and the other a point on its longitudinal surface, a strong variation of the needle ensues, the current going from the external longitudinal surface to the transverse. The external surface is therefore positive (+) towards the transverse, which is negative (-) in its electric relations. If both wires be placed on the surface of a nerve, one nearer the centre point (equator) than the other, a weak current is produced, going from the point nearest the equator towards the point at a distance from it. A point near the centre point of a nerve is therefore positive towards a point at a greater distance from it. In muscle the same relations are found to hold in two points of a transverse section."

"The theory of Du Bois to explain these effects may be thus stated:—Every minute particle of nerve acts according to the same law as the whole nerve. A nerve consists of a number of di-polar molecules, one half presenting positive, the other half negative electric properties. These di-polar molecules are arranged in couplets, and so that the positive poles are turned towards each other, their negative poles to the extremities of the nerve. Each couplet of molecules produces currents going from the central positive poles to the negative poles. A nerve is always in the condition of a closed current, and when the extremities of the wires of the gal-

vanometer are applied, a part merely of the current is abduced.

"The foregoing facts and theory apply to a nerve when it is in a state of rest. When a constant galvanic current is made to pass through part of a nerve, an electrical change takes place, to which the name electrotonus is applied. Supposing that while a piece of nerve is placed on the cushions of a galvanometer, and a constant deflection of the needle is produced, a constant current be passed through this piece of nerve in the same direction as the nerve current, then an increase of the deflection of the needle is observed. This is termed the positive phase of electrotonus. If a constant current be applied in a direction opposite to that of the nervous current, the deflection of the needle is decreased, and this is termed the negative phase of electrotonus. If a nerve be placed with its equatorial point exactly between the cushions, so that no deflection is produced, and if a constant current be now applied to the nerve, a deflection of the needle will take place, its direction being determined by that of the applied current. Such are the principal facts of electrotonus, and the explanation of them furnished by Du Bois is the following. When any portion of the length of a nerve is traversed by an electric current, besides the effect of the original nerve current, a new electro-motive action takes place, which has the same direction as the applied current. This new current is added to the original nerve current if the direction be the same, but subtracted from it, if the direction be opposite."—British and Foreign Medico-Chirurgical Review, &c., Lon., July, 1862, p. 6, 7.

Admitting all the foregoing facts, and others of a corresponding nature, to be well ascertained, they can in no respect affect the validity of that other and vast series of facts presented in these Institutes which contradistinguish the nervous power from electricity, nor can imagination conceive of the functions of the latter when the phenomena of animals, physical and mental, and of plants, are consid-

ered according to their realities.

Note Z.—Uræmic Poisoning. An experiment by Bernard (§ 1032 d) disproves uramia, and shows that diseases of the brain, and merely sympathetic influences upon it, and mental emotions, may so affect the kidneys that they shall not only fluentate greatly in their excretion of urine, but may generate irritants that stimulate the bladder to frequent micturition. It is not improbable that diabetes is greatly owing to influences of the nervous system upon the kidneys, which would show us that the sugar does not exist in the blood (§ 1032 a).

NOTES TO THE EIGHTH EDITION.

The following Notes are added to the Eighth Edition of this Work, and references to them are introduced in appropriate places in the text.

NOTE AA.—PHYSIOLOGY OF THE CEREBRO-SPINAL AND SYMPA-THETIC NERVES.

There appears to be nothing in the researches into the functions and laws of the nervous system since the last edition of this work that can in any respect modify the statements and the philosophy as herein presented, but, on the contrary, go to their confirmation. Among the most intricate experiments, and corroborative of distinct orders of nerves as set forth in sections 197-201, 224, 446-447, 500 g, nn, 893 a, 8931, 1037 b, may be mentioned some late ones by C. Bernard upon dogs, in continuation of others performed several years ago, from which he deduces, as a general fact (and in conformity with results that had been already obtained by others), three distinct varieties of nervous influences, according to the origin, composition, and distribution of the nerves. Thus, in some late experiments upon the extremities of dogs he found, besides the motor influence for the voluntary muscles which is imparted by the anterior roots of spinal nerves, and the sentient influence which belongs to the posterior roots (§ 1037 b), that the vascular and calorific influence appertains entirely to the sympathetic nerve. These distinctions are fundamental throughout the Institutes. That which relates to the sympathetic nerve is mostly important, as through that I have interpreted all the influences upon organic functions and their results, whether in a physiological, pathological, or therapeutical sense, so far as nerves are tributary, and which, also, I have employed extensively in exposing the fallacies of the chemical and humoral doctrines.

Besides the foregoing distinctions there should be added the motor nervous influence for the muscles of organic life, which is imparted by the sympathetic nerve, and which is quite distinct from that which relates to the proper organic functions, since, as it respects its agency in exciting the action of the organic muscles it is on common ground with the motor influence of cerebro-spinal nerves, and goes no farther, while the same nerve exerts a special modifying influence upon the vascular system, upon all organic functions, and modifies the organic products (\S 111–113, 224, 356 a, 394–396, 446, 455 a, 459 f, 461, 461 $\frac{1}{2}$, 473 c, 475 $\frac{1}{2}$, 478 b, 483 c, 488 $\frac{1}{2}$, 500 g, m, nn, o, 516 d Nos. 7–9, 524 d No. 7, 647 $\frac{1}{2}$, 889 g, 893 a, c, 893 $\frac{1}{2}$, 1044).

NOTE BR.—CAUSES OF THE HEART'S ACTION.

In respect to the doctrines of the dependence of contiguous sympathy upon ganglia and other local centres of the sympathetic nerve, and of the operation of vesicants, setons, etc., through those local centres, and of the independence of continuous sympathy or continuous influence of the nervous systems advanced in sections 129 f, 264, 475½, 498 e, 514 f, 515, 516 d No. 7, 893 a, c, 905 a, etc., it may be of interest to state the following conclusions obtained by Golz as to the instrumentality of the ganglia in the heart's action: 1. "The pulsating parts of a frog's heart constitute together a system of small independent apparatuses, each of which is possessed of a ganglionic central organ (§ 516 d No. 7). 2. These small nervous centres can be excited to action by various stimulants, and this action, according to its intensity, manifests itself in more or less protracted contractions of the muscles which are governed by the stimulated centre. The natural stimulus which incites the ganglia is the blood (§ 475½). 3. A sudden contraction of any part of the heart acts slightly stimulating upon the neighboring parts. Thus, when a stimulated part contracts, the contraction spreads like a peristaltic movement, according to the laws which depend on the connection of the nerves with the ganglia. 4. The reason why the heart contracts rhythmically is, perhaps, to be found in the following circumstance: As soon as the stimulating influence of the blood is powerful enough to act upon the ganglia, the systole at once commences, and emptying the heart, removes from it the stimulating cause" (§ 264, 383-386, 392-395, 4751, 514 f, 516, 1090).

NOTE Cc.—WHOOPING COUGH—THE PHILOSOPHY OF ITS TREATMENT.

I have expounded the physiological influences through which the act of vomiting will suddenly arrest a paroxysm of coughing, as witnessed in whooping-cough, for the purpose, particularly, of demonstrating by a distinct example the operation of emetics in organic life, through their action upon the organs of animal life, by the instrumentality of the nervous system, and thence showing how these simple examples may be employed in interpreting the analogous results of remedial and morbific agents in their removal or production of disease (Index II., Whooping-cough, Hiccough, and Hysteria). It will be seen that the example is parallel in its intended illustrations with many others which occur in this work, as in sections 500, 514, 516,

 $902 \ g-m$.

As it respects the interruption of the cough by vomiting, the emetic influence is exerted upon the organic nerves of the gastric mucous tissue, while the point of departure for the excitement of the nervous influence that determines the cough is in the same nerves in the pulmonary mucous tissue, and in both cases the motor nerves belong to the cerebro-spinal system, and are implanted in the thoracic and abdominal muscles, and diaphragm (§ 514 b). Now, as I have said, whatever will excite vomiting during a paroxysm of coughing, even when produced by the cough itself, will at once interrupt the latter by so modifying the development and reflection of the nervous influence as to introduce a new combination of movements in the respiratory muscles (\S 514 c). If the vomiting be occasioned by the cough, or by tickling the throat, or by a mental emotion (Note D, p. 1114), or by warm water, or by an infusion of mustard-seed, the effect will go no farther (§ 902 h). To obtain, therefore, any influences from emetics upon the morbid conditions in whooping-cough, they must possess also other virtues than such as determine the act of vomiting, and it is through the special impression which those virtues make upon the gastric mucous tissue that such emetics simultaneously reflect an alterative nervous influence upon the absolute pathological conditions (§ 233 $\frac{4}{5}$, 500 g–l, 514 f, k, 902 d–m, 1059). The best emetics for this combined purpose, and indeed the only ones for the alterative influence, are tartarized antimony and ipecacuanha. But in cases to which these are appropriate, their gradually alterative impression, as effected by small and repeated doses just short of nausea, is generally more salutary than emetic doses at distant intervals, since no greater extent of the remedy is commonly necessary in whooping-cough to bring about vomiting, as it is the tendency of the cough to reflect an emetic nervous influence upon the gastric mucous membrane, which will be likely to determine the act of vomiting when the same membrane is slightly predisposed by the irritating virtue of an emetic (§ 514 b, 516 d No. 6, 657 a, 889 a, f, g, 902 e-i, 904 bb, Note D, p. 1114). The same philosophy is applicable when an emetic interrupts a paroxysm of spasmodic asthma or of hysteria (§ 514 c, $891\frac{1}{2}$ c, f, k).

NOTE DD.—LEECHING, PHILOSOPHY OF ITS EFFECTS, HOW FAR DEPENDENT UPON VASCULAR COMMUNICATIONS.

Dr. William Turner appears to have demonstrated the very interesting fact of the existence of a system of anastomosing arteries between the visceral and parietal branches of the abdominal aorta, and which is likely to be followed by some highly practical advantages. This will be apparent from a remark which Dr. Turner makes in connection with his ingenious demonstration. "This assumption," he says, "of the absence of any direct communication between these two sets of vessels has been employed by some physicians as a principal argument against the utility of local bloodletting in the treatment of inflammation of the abdominal viscera. Bennett's Clinical Lectures, 1859, p. 280."—This common objection is founded upon the universal mechanical philosophy of the modus operandi of loss of blood when artificially effected—a philosophy which excludes all the magnificent laws in physiology both as it respects the nervous influence and the organic endowments, and their involutions as instituted by the incidental operation of physical and mental causes, and is regardless of the inexhaustible testimony of the most enlightened experience (§ 910). But, although it is probable that the foregoing objection to leeching will yield to the anatomical fact demonstrated by Dr. Turner, the fact itself does not supply a ray of light to the mechanical Physicians, since the intercommunication

of the inosculating vessels is wholly insufficient for the hypothesis which supposes a diversion of blood from the internal organs to the very limited space over which leeches are applied, nor does the inosculation any more explain the operation of counter-irritants upon deep-scated inflammations; and the solution, therefore, which I have made of the resulting phenomena, whether of leeching or of counter-irritation, through the medium of the nervous system, will remain the only intelligible theory (§ 893 a, c, 905 a, 915–924, 942 b). As it respects the law of continuous sympathy, its operation, in leeching, when involving only the bloodvessels, is limited to the vessels of the skin, and is more or less circumscribed, according to the number of leeches, and the special circumstances of every case. When the bloodvessels alone are interested, the propagation of this continuous influence along their course is of very little moment excepting as it is tributary to reflected actions of the nervous centres (§ 498, 917, 919).

NOTE EE.—THE REMEDIAL VIRTUES OF ANTIPHLOGISTICS AND TONICS CONSIDERED RELATIVELY.

The almost endless variety of virtues which appertain to the remedies that are . adapted to the treatment of inflammations and fevers, or which may be created by uniting two or more of them together, and also according to the proportions of each constituent (§ 860, 863 d, 872 a, 889 k, 892 b, $892\frac{1}{4}$ a, 1058, 1060-1065), contrasted with the single property that alone characterizes, as a remedial virtue, any member of the groups of tonics and stimulants, should assure us that the former are designed for the multifarious conditions of inflammatory and febrile diseases, while the latter is equally pronounced, by its solitary virtue, to be suited only to such forms or conditions of disease as are nearly allied to each other (§ 890} a, h), and where, by common consent, the remedies that are deficient in that special virtue have comparatively little or no tendency to introduce the restorative process, but, on the contrary, generally aggravate the conditions which the stimulants relieve. The phenomena which ensue upon the operation of tonics and stimulants, whether of a salutary or morbific nature, are the same, respectively, throughout; and, although loss of blood, cathartics, emetics, the mercurial and antimonial alteratives, blisters, and other things belonging to the class of antiphlogistics, will alike make their salutary invasions upon all forms of inflammation and fever, yet in all the cases there is not only a want of coincidence in all the direct manifestations, but the greatest diversity scarcely any thing in common beyond the subsidence of disease (§ 900, 1059, 864).

Since, therefore, it is abundantly evident that the great varieties of remedies denominated antiphlogistics, ranging from loss of blood, cathartics, emetics, mercurials, antimonials, vesicants, and other agents that are adapted to the common form of inflammation and fever, to iodine, cinchona, arsenic, cobweb, colchicum, veratria, etc., which are suited only to the specific forms, are endowed with an incalculable variety of remedial virtues, and, also, that their combinations, both as to the number and nature of the constituents and the proportions of each, extend the variety of their virtues indefinitely (§ 872), while, on the other hand, tonics and stimulants possess but a single virtue in their relation to disease, and are incapable of yielding any new ones by their combinations, or of displaying any of the variety of effects common to the antiphlogistics by simply varying the doses (§ 516 d No. 6, 1057½), it needs no farther demonstration to show that the former are intended in Nature for a vast variety of pathological conditions, while the latter are as distinctly limited to the simple office of reviving the exhausted or the prostrate powers of life.

The foregoing comments have grown out of the numerous contrasts that have been instituted in this work between antiphlogistics and stimulants; and I am finally led to consider a principal reason for the remarkable ascendency which the stimulating practice has obtained at this advanced age of knowledge. The recital will be at least interesting to the future historian, and can not fail of a useful effect upon the "Divine Art." The foundation of the evil is variously presented in these Institutes, which may be briefly said to consist of the physiology which has been proclaimed from the laboratory of the Chemist, and the pathology which has sprung from the same factitious pursuits, and a reliance upon morbid anatomy and the microscope, to the exclusion, in all this vast and diversified field, of the signs and philosophy which distinguish organic nature in its living condition. The absence of principles, therefore, leaves the Profession as much without a guide in practical medicine as the mariner at sea without his compass.

This brings me to an important practical comment upon the revival of an old doctrine which has been lately inculcated by many distinguished medical writers, and extensively accepted by the Profession—formerly called "a meditation upon death." Say they: "Diseases can not be arrested at any stage of their progress, even at their earliest, unless it be some special form, like the intermittent fever, where an antidote has been discovered for the blood poison." Hence the dogma has arisen that tonics and stimulants are all that can be usefully employed, with the object of "sustaining Nature while she is engaged in climinating poisons from the blood," or in some analogous office, and therefore, also, that bloodletting, catharties, and other depressing means must be injurious. This logic is at the foundation of a vast amount of practice.

The important question now arises as to the real origin of the dogma that most, if not all, diseases run an indefinite course of rise and decline in spite of all remedies and the best directed skill. The answer is to be found in the pernicious effects of the tonic and stimulating treatment, since, as I have variously shown upon the soundest principles, and by the authority of all the best experience from the day of Hippocrates to our own, that method of treatment prolongs all acute maladies till the morbid process may succumb to the physiological laws of recuperation (§ 756 a, 853, 856 a, 863 h), when tonics and stimulants may yield an advantage that has led, under these delusive circumstances, to their employment at the early stage of disease. The curious fact, therefore, presents itself, that the stimulating practice began at an early period of disease quickly confirms the morbid process, and thus contributes, along with the neglect of appropriate remedies, to the conclusion that all disease terminating favorably run on until they run out; while the same treatment, continued after recuperative nature may have struggled successfully against it, is

supposed to have been tributary throughout to the fortunate issue.

This all-pervading school (permitted, perhaps, as an auxiliary means in the dispensations of Providence) is naturally sustained by the prejudices and propensities of the community, which render it less susceptible of reformation. But it suffers in its dimensions by many seceders, whose experience with the stimulating treatment had equally enforced the conclusion that diseases can not be stayed in their progress toward a natural termination, and that tonics and stimulants fall under the category of all other remedies, and who, therefore, insist that Nature should be left to the simply watching system (§ 878), or at most to the aid of tonics and stimulants when her resources become apparently exhausted. Occasionally, also, disciples of the stimulating school are prompted by their unfortunate experience to try the method at which they had so long revolted, and if they venture as far as copious bloodletting, and purging, in grave inflammations and congestive fevers, they are astonished to find that all these diseases may be suddenly arrested at their early stages, and that life should be thus as uniformly saved as it had been as uniformly lost by the stimulating treatment—nor are there wanting illustrious examples to whom these remarks apply (§ 1005 a–h, Note Fr).

I do not flatter myself that what I have now and hitherto said on the foregoing subject will exceed the usual small allotment in advancing the interests of truth in its conflicts with error. They are arrayed in uncompromising hostility, and however powerful may be the weapons of the one, they are wielded by a few against a multitude who are intrenched in the fortress of "Common Sense," and rejoice in the delusion of vox populi vox Dei. Simplicity and plausibility are the triumphant advantages of error. A single fact that addresses itself strongly to the senses often outweighs a multitude of contradictory ones which can be developed or appreciated only by patient research and profound meditation. This contrast between truth and error may be well exemplified by the apparent and real motions of the heavenly orbs. "Common Sense" assumes that the earth is stationary and that the heavens revolve about it; but reason, through its profound investigations, decides that "Common Sense" is in error. But ages elapsed, and an incalculable amount of intellectual labor was brought to the subject before the error could be dispelled. Indeed, it is said that, even at this age, the "Doctors of Salamanea" daily crucify Galileo, greatly preferring the promptings of Sense to the difficult revelations of science (§ 1 b, 5\frac{1}{4}c).

And just so it is with whatever is true or false in medicine. With the multitude "Common Sense" is forever the victim of appearances. It believes, for example, that "debility" is the essence of disease, having no conception that it is a mere symptom, and no reference to the latent causes upon which it depends and which alone should guide the practitioner. "Common Sense" is also greatly responsible

for the delusions with which Humoralism and Organic Chemistry have vitiated medical science. Nothing, for example, can be plainer than that the matter of eruptive diseases comes from the blood, and, therefore, Common Sense, according to its usual superficial manner, argues that the blood is the essential seat of the malady, and that tonics and stimulants are alone wanted "to sustain the strength while the blood is casting off its impurities." Upon the same ground, "blood poison" is the descriptive phrase for the whole pathology of typhus, intermittent, yellow, and other fevers, for which the same sustaining treatment and its philosophy obtain; or here quinine is supposed to neutralize the reputed poison, or, at other times, and in other maladies, iron is a favorite to "enrich the blood," or iodine as a peculiar purifier (Notes K, N, R). And this, according to the "recent progress of medical science," about exhausts the Materia Medica. As an example of "the progress," calomel and tartarized antimony are excluded by the Surgeon General, Dr. Hammond, from the armies of the United States of America. Calomel is forbidden, he proclaims, "with the more confidence, as MODERN PATHOLOGY [!] has proved the impropriety of the use of mercury in very many of those diseases in which it was formerly unfailingly administered." And this is only a little more arbitrary (because sustained by military power) than the general policy by which Humoralism and Organic Chemistry have nearly crushed out all that is most valuable in medical science ($\S 5\frac{1}{2} a$, 819 b). If Solidism raise its voice in solemn protest, "Common Sense" points to debility, or to pustular eruptions, or to vitiated secretions, and curls its lip at whatever is grand, and magnificent, and practical in the laws of the organic functions and of the nervous systems. But nothing is more certain in the future than that, "ere the account be closed, principles will stand for something, and conscience, as in all human affairs, will have the last word."

NOTE Fr.—BLOODLETTING IN YELLOW FEVER, AND IN OTHER CONGESTIVE FEVERS, CONTRASTED WITH THE STIMULATING TREATMENT.—NO CHANGE IN THE TYPE OF DISEASES.

Besides the great amount of enlightened experience which this work supplies upon the importance of Bloodletting in Yellow Fever (§ 959 b, 992 a, b, 993, 999, 1002, 1004, $1005\frac{1}{2}$), and more particularly the Medical and Physiological Commentaries, the unexampled fatality of that disease in recent times (so manifestly arising from the stimulating treatment, § 1068 b), leads me to some specific statements as to the quantity of blood which was often found necessary to the best success in the epidemics which visited Philadelphia toward the close of the last century, while it will be also seen that the principal physicians of that city applied the remedy to an extent demanded by the exigencies of the disease. Nevertheless, the tonic and stimulating treatment prevailed at first, universally, and had then, as now, no reference to the essential condition of the disease, but was, equally as at this day, addressed to that superficial symptom debility, which, in its popular acceptation, is attendant upon all diseases (see INDEX II., DEBILITY). It is, indeed, for the reason that the symptom is supposed to constitute the disease that tonics and stimulants are now the only remedies, in a general sense, that are in the hands of the profession, and the antiphlogistic condemned as unwarranted by this leading principle in pathology. it is a more inexplicable paradox that the mortality attending the stimulating treatment does not oftener appeal to the judgment or the conscience of these triflers with human life. The annals of medicine supply but few examples of an abandonment of a practice which has constantly illustrated its own errors and the dogma upon which it has been founded. These few are mostly limited to able thinkers, who are quoted in this work (§ 1005 a-h). Rush has supplied, in his Medical Inquiries and Observations, a few instances that were signalized by the yellow fever of 1793. "Dr. Pennington," he says, "informed me that he had lost all the patients to whom he had given bark and wine. Dr. Johnson assured me, with great concern, about two weeks before he died, that he had not recovered a single patient by them. Whole families were swept off where these medicines were used. There was not a single cure performed by them in New York, where they were used in several sporadic cases with every possible advantage. But why do I multiply proofs of their deadly effects? The clamors of hundreds whose relatives had perished by them, and the fears of others, compelled those physicians who had been most attached to them to lay them aside, or to prepare the way for them, as it was called, by purging and bleeding." The physicians who adopted the latter practice "gave calomel by itself, in small doses, on the first or second day of the fever, bled once or twice in a sparing manner, and gave the bark, wine, and laudanum, in large quantities, upon the first appearance of a remission. This practice was not much more successful than the purely stimulating. It resembled throwing water and oil at the same time upon a fire in order to extinguish it." Nothing, indeed, succeeded but decisive bloodletting and purging with the right cathartics. This was farther illustrated by the French practice, of which the following is an example. The hospital at Bush Hill, "where most of the patients were sent in the first stage of the fever, and provided with all the necessaries and comforts that humanity could invent, or liberality supply, was placed, after September 22d, under the care of a French physician, who employed moderate bleeding, and purging with salts in some cases," and also "nitre, cream of tartar, camphor, centaury tea, and tamarind water," but no bark and wine. The result was that the deaths between September 22d and November 6th amounted to 448 out of 807 patients who were admitted into the hospital within that time. "Three fourths of all the blacks (nearly twenty) who were patients in this hospital died;" while Dr. Rush remarks, in another place, that "a great number of the blacks were my patients, and of these not one died," under his treatment of bloodletting,

and purging by calomel and jalap (863 d).

Of the practice of "moderate bleeding" Dr. Rush remarks that "an increased action of the bloodvessels was the consequence (§ 965 b, 985 b), and thus complaints of the chest and head were made worse by a single bleeding. This excited or strengthened the prejudices of patients and physicians against it" (§ 1000–1001). These patients died, and are among the multitude of instances which sustain the enlightened experience already quoted (§ 994–1001, 1005). Sydenham makes the same affirmation of the plague. "It is not at all surprising," he says, "that bleeding in a small quantity should be always prejudicial; but I appeal to the physicians who continued in town during the late plague (London, 1665 and 1666), whether free and repeated bleeding, before a swelling (bubo) appeared, was ever observed to prove fatal to any of the infected," He speaks of the opposition to bloodletting as "a vul-

gar prejudice" (§ 1000).

It is remarkable that Dr. Rush should have begun the treatment of the yellow fever of 1793 by tonics and stimulants-"bark, wine, brandy, and aromatics." after a disastrous experience, he confesses, with much lamentation, to a total failure; and his conversion to bloodletting, and purging with calomel and jalap, and the triumph particularly of the former remedy, are so coincident with the experience of Hey, Gordon, Denman, and Cleghorn, as related in section 1005, that they may well be incorporated in that category of frank confessions of disastrous experiment leading to the recognition of philosophical principles and triumphant success. "Heaven alone," says Dr. Rush, "bore witness to the anguish of my soul in this awful situation. But I did not abandon a hope that the disease might yet be cured." Among the causes of his substitution of bloodletting for stimulants "were frequent hemorrhages from every part of the body;" and while they afforded "perfect relief" at advanced stages of the disease, "not a single death occurred from natural hemorrhages in the first stage of disease" (§ 805, 863 a-h, 1018). He felt his way, however, cautiously, thus manifesting that predilection for the fatal practice which we have seen to be true of other converts till aroused by the havoc it produced (§ 1005 a-h). "I began," he says, "by drawing a small quantity of blood at a time." This "satisfied him of its safety and efficacy," and he grew bolder. "Never before," he says, "did I experience such sublime joy as I now felt in contemplating the success of my As an evidence of this he makes an extract from his note-book, dated September 10th: "Thank God! out of one hundred patients, whom I have visited or prescribed for this day, I have lost none" (§ 1004 c). The sunken pulse and prostrated strength rose under repeated abstractions of blood (§ 961, 967, 1004 b). paid no regard," he says, "to the dissolved state of the blood when it appeared on the first or second day of the disease, but repeated the bleedings afterward in every case where the pulse continued to indicate. It was common to see sizy blood succeed that which was dissolved." "The presence of petechiæ did not deter me from repeated bloodletting where the pulse retained its fullness or tension" (§ 1002 d-f). "I bled many patients twice, and a few three times a day" (§ 999 a, b). "I did not lose a single patient whom I bled seven times or more in this fever." "I cured" (after he had abandoned tonics and stimulants) "a greater proportion than ninetynine out of a hundred of all who applied to me on the first day of the disease, before the 15th day of September" (§ 557, 861). "After the 15th my success was much limited compared with what it had been before that time. But at no period of the

disease (with the qualification aforesaid) did I lose more than one in twenty of those whom I saw on the first day." "The number of deaths between the 1st of August and the 9th of November amounted to 4054." Notwithstanding, however, the stimulating practice obtained with many of the physicians throughout the greater part of the epidemic, Dr. Rush remarks that "not less than 6000 of the inhabitants of Philadelphia probably owe their lives to purging and bleeding during the autumn." "Many whole families, consisting of five, six, and, in three instances, of nine members, were recovered by plentiful bleeding and purging." Other physicians gradually adopted the depletive treatment, "one of whom cured ten in the family of Mr. R. Haydock by means of the remedies." "Dr. Pennington" (who had lost all the patients to whom he had given bark and wine) "assured me on his death-bed that he had not lost one out of forty-eight patients whom he had treated agreeably to the principles and practice I had recommended. Dr. Griffiths triumphed over the disease in every part of the city by the use of what were called the new remedies." Of his own success in the epidemic of 1797 he says, "I lost but one patient who had been the subject of early and copious bleeding. His death was evidently induced by a supper of beefsteaks and porter during convalescence."

To the untiring perseverance of Dr. Rush is due the overthrow of the stimulating treatment, which reckoned almost every patient as its victim, as shown by the success of the antiphlogistic practice. That fearless man, in the midst of great obloquy, "defended his treatment in the public papers against the attacks that were made upon it by several of the physicians of the city." "This controversy with my brethren," he adds, "with whom I had long lived in friendly intercourse, carried on amid the most distressing labors, was extremely painful to me." But he finally triumphed, and his memory presents an imposing contrast with that of his opponents. The disastrous effects of the bark and wine treatment "in some of the most opulent families in the city, and the almost uniform success of the depleting remedies, happily restored the public mind, after a while, from its distracted state, and procured a submission to the latter from nearly all the persons who were affected with the fever." Of the epidemic of 1794 he remarks that, "in Philadelphia and Baltimore, where bleeding and purging were used in due time, and as I have described, not

more than one in fifty died of yellow fever." "In 1797 the stimulating mode was de-

serted by every physician in the city."

In regard to the quantities of blood which were often abstracted, the following are examples in the epidemic of 1794. Dr. Rush supplies a table of 23 cases in his own practice, in which the quantities varied from 50 to 150 ounces, "taken in three, four, and five days." "I did not cure a single person," he says, "without at least one bleeding." In the epidemic of 1793 he has examples to the extent of 100 ounces at repeated bleedings. In the epidemic of 1797 he mentions five individuals whom he bled to the extent of more than 100 ounces. In the same epidemic "Dr. Dewees bled Dr. Physic 176 ounces; Dr. Griffiths bled Mrs. Thompson 110 ounces; Dr. Stewart bled Mrs. M'Phail 106 ounces; Dr. Cooper bled Mrs. Evans 150 ounces; and Dr. Gillespie bled himself 103 ounces. All these persons had a rapid recovery" and Dr. Gillespie bled himself 103 ounces. All these persons had a rapid recovery" (§ 992, 994). In the epidemic of 1798, "Dr. Mease was bled 162 ounces, and Mr. J. C. Warren 200 ounces," and recovered. When bleeding had been neglected in very prostrated cases, "Nature often performed that operation upon herself from the gums on the fourth or fifth day. I have seen several pounds of blood discharged on those days with the happiest effects. It appeared to take place after the revival of the bloodvessels from their prostrated state" (§ 805, 863 f, 890 d-g, 961-964, 984 c, 1018-1019, Notes Gg, II). In the epidemic of 1799 "there were few cases that did not indicate bleeding. Mr. Rowan lost 200 ounces of blood by 22 bleedings" (§ 999 a, b).

If we now compare the mortality from yellow fever that has distinguished the tonic and stimulating treatment for the last forty years with the results of the stimulating and antiphlogistic methods of the last century, it will be seen that the profession is again called upon to return to principles, and to that enlightened experience from which the principles have been deduced (§ 1004 a), and to surrender the prejudice that the same diseases so fluctuate in their type in different countries and at different seasons as to require opposite modes of treatment (\S 752-756, 960 g,

969 d, 1006 a-g, 1068).

NOTE GG.—BLOODLETTING IN DYSENTERY.

This note is in connection with § 863 f, 890 e, 984 c, 991 b, 1019, 1058 f, and Notes F, Ff. In Note F I had occasion to quote the high authority of the British and Foreign Medico-Chirurgical Review in proof of the disastrous effects that have resulted from the abandonment of bloodletting in the early stages of diseases of the lungs, and it is now my purpose to quote the same authority to show as remarkable a contrast between the results of the treatment of dysentery by bloodletting, calomel, opium, etc., as practiced during the British naval expedition to China in 1840-'42, and which "was most in vogue twenty years ago," and the treatment adopted during the second expedition for the three years 1857, '58, '59. Thus the Review:

"Of late years (and during the second expedition) the heroic or active treatment by depletion, etc., has fallen into desuetude, and reliance has been placed on milder measures. Ipecacuanha, in the manner recommended by the Indian practitioners, has been largely tried, together with hydrarg, cum creta, opium, the mineral acids, topical bleeding, counter-irritants—in short, all the older remedial agents, excepting

general bloodletting and calomel."

Now, says this able digest of the "Medical Results of the recent Chinese Wars," "By presenting the products respectively in the form of figures, the mind will seize at a glance the painful disparity.

Years.	Number of Men employed.	Cases of	Number invalided.	Number died.
1840-1-2	15,470	Dysentery. 2102	60	188
	24,980	2006	606	465

Thus, in rough numbers, in the first Chinese war, one out of every eight and a half of the men attacked succumbed or was disabled from service; in the second Chinese

war, one out of every two."

It appears, therefore, according to the foregoing account of the treatment, that the "painful disparity" is to be attributed to the neglect of general bloodletting, since the other "theroic remedy," "calomel pushed to ptyalism," has been only an occasional remedy for dysentery—never, indeed, much practiced either in Europe or America. But, more than all, I am most happy to hail a returning appreciation of the accumulated experience of the past (though it be the slow result of "a painful disparity"), as expressed in the following quotation from the article to which I am indebted, and which was contributed to the Review by T. Nelson, M.D., Staff Surgeon, R.N.

disclosed, the conclusion to which they lead can not be avoided, namely, that the recent method of treatment of dysentery in China, so far from having become more successful from the additional experience which twenty years confer, has, on the contrary, very decidedly retroceded. In presence of this painful but inevitable inference, it becomes a subject for serious consideration whether the much contemmed practice of twenty years ago has not been superseded somewhat rashly, for another which, conforming to the quietism of the day, has brought about a series of results that in these times has no parallel" (§ 1005 b-h, Note Fr).—British and For. Med. Chir. Rev., July, 1863.

In the last conclusion the writer is mistaken as it respects the relative excess of mortality from other modes of treating dysentery, for the stimulating and astringent method, now in vogue, supplies a "more painful disparity" than the simple exclusion of general bloodletting from the antiphlogistic treatment practiced by the Brit-

ish surgeons during the second Chinese expedition.

NOTE HH.—MEMORY SUDDENLY LOST, AND SUDDENLY RESTORED BY FREE BLOODLETTING.

On the 26th of October, 1862, at eight o'clock A.M., I was requested to visit Dr. O. B., a medical gentleman of this city, who had sustained, in the course of the preceding night, a loss of memory. I had passed the evening in conversation with him, at which time his memory was perfect, and he had been attending to his usual avocations abroad during the day. His age was about 62 years, slender in his person, and he had suffered in former years much infirmity of health, which was still habitually delicate. The case presented some very remarkable intellectual phenomena;

and I record it not only for that reason, but in farther defense of the great remedy against which so insane a prejudice prevails. It goes, moreover, with the rest in showing that diseases do not fluctuate in the supposed manner in their pathological

conditions (§ $1005\frac{1}{2} a$, 1068).

The case presented a total obliteration of memory as to the past and passing events, but it was sufficient for a connected association of ideas, and reason was apparently sound as it respected subjects immediately present to the mind. His remarks referred alone to the occurrences of the moment. As examples of the failure of memory, the doctor had no recollection of my visit on the preceding evening, and when this information was repeated several times in as many successive minutes, it was already lost to his memory. And so of other things, upon which he would reason correctly, but would totally forget the conversation and the subjects about as quickly as the words succeeded each other.

I was informed by his family that he had complained for ten days of some headache, but that in other respects he had made no unusual complaint of his health. His pulse was about ninety strokes in a minute, full, strong, and rather hard and incompressible (§ 688 d, e); tongue clear, appetite unimpaired, muscular strength undiminished, skin natural. He had arisen from bed at his usual hour. Of the headache he had no recollection; and the only circumstance which reconciled him to medical treatment was the full consciousness that he had lost his memory. And yet this consciousness existed only at the moment when his attention was brought to the subject. And so, also, in respect to the treatment. When bloodletting was proposed he raised objections to the remedy, but would forget within a minute that it had been the subject of discussion; and even, at last, when the preparation for bleeding was ready, he was astonished at being informed that it was my purpose to

bleed him, and that he had not been consulted upon the subject.

The pathological condition, in my judgment, was venous congestion of the brain such as is apt to result in apoplectic attacks. I therefore anticipated the best results from the remedy, and that the system would bear a free abstraction of blood under the stimulating nervous influence developed by the cerebral excitement (§ 975, The patient sat in a chair, and thirty-two ounces of blood were abstracted, when the radial pulse had yielded sensibly in force, fullness, and frequency, with other indications of approaching syncope, which, however, did not ensue. While the blood was running I gave particular attention to the state of the mind, and ascertained that the memory was progressively returning, and it was completely restored within an hour after the blood had been abstracted. The patient continued to move about the house during the day, and about the city in two days afterward. He had no more headache, and no medicine was administered. There has been now an interval of about two years, and there has been at no time any manifestation of "debility," but rather an improved vigor of health. Nor has there been any disturbance of the memory, though it is an interesting fact that the doctor remembers nothing of the occurrences of the morning of the 26th of October prior to the abstraction of the blood (§ 1072 b, 1078 o).

NOTE II.—INTESTINAL HEMORRHAGES CURATIVE IN TYPHUS FE-VER, ETC.—IDENTITY OF TYPHUS AND TYPHOID FEVERS.

Notwithstanding the accumulated experience, throughout all the ages of Medicine, of the salutary effects of spontaneous hemorrhages, particularly as incident to congestive fevers, the following statement, being comprehensive and one of the latest, may be usefully added to the other evidences upon that subject recorded in this work. At a meeting of the New York County Medical Society, held March 2, 1863, Dr. H. D. Bulkley, a physician of learning and ability, remarked that,

"With regard to the value of intestinal hemorrhages in typhoid fever, Drs. Bretonneau, Chomel, Louis, and others, considered this a dangerous symptom, but that Dr. Graves thought it rather favorable than otherwise, provided the loss of blood was not extreme. M. Trousseau was at first surprised at this opinion of Dr. Graves, but finds, on looking over his cases, that in seven years he has known but two deaths from such hemorrhage. Others attacked with it not only recovered, but were better afterward. Dr. Ragaine, in a memoir on this subject sent to the French Academy, relates one hundred and fifteen cases of typhoid fever, of which eleven suffered from hemorrhage, and they all recovered" (§ 805, 863 e, f, 890 e, 922, 984 c, 1002 f, 1006 d, g, 1017 b, 1018-1019, 1068, Notes F, FF, GG)

In respect to the identity of typhus and typhoid fevers, as shown in Note S, it may be farther stated that on the foregoing occasion, "Dr. Bulkley considered typhus and typhoid fevers as varieties of the same disease;" that "Dr. Finnell maintained his belief in the identity of typhoid and typhus fevers;" and that "Dr. J. Foster considered the two types as one and the same malady"—all the gentlemen deducing their conclusions from personal experience.

NOTE KK.—DIPHTHERIA.

A brief reference to this complicated disease is made in a note at page 350, and at page 450, \S 689 I, for the purpose, especially, of indicating the pathology of the disease; and it is now my object to reproduce those considerations in connection with the very fatal effects of the almost universal treatment of the epidemic by tonics and stimulants, and to commend to the Profession what appears to me to be the only method which is warranted by the general and the local pathology, and which, in my hands, has been attended by speedy relief, even in infancy—that is to say, the strictly antiphlogistic. Decisive bloodletting, either by the lancet or by leeches, is generally indispensable; after which a moderate dose of calomel, or of blue pill, to be soon followed by castor oil, or the oil without the mercurial remedy (\S 1057 I), will be about all of an active nature that can be advantageously done.* The superficial hypothesis of debility is the source of the appalling mortality, and is of the same nature as that which is examined in sections 487 h, 569 b-e, 621 a, 743, 752–756, 785, 815, 887, 961–970 c, 992 c, 999 c, 1005 b-h, 1006 f-1007 b, 1068 a b, Notes F, Fr.

NOTE LL.—THE PULSE AS A GUIDE TO BLOODLETTING.

It is a remark of Dr. Rush that "where all the different states of the pulse which indicate the loss of blood are perfectly understood, and bloodletting conformed in time and quantity to them, it never can do harm in any disease. It is only when it is prescribed empirically, without the direction of just principles, that it has ever proved hurtful."

The foregoing statement occurs in Rush's account of the yellow fever of 1794, and in his "Defense of Bloodletting" he mentions particularly, in the form of very brief abstract rules, ten different "states of the pulse that indicate the necessity of bleeding." It may be safely said, however, that the "necessity" can not be inferred from any one of the conditions without the light of other symptoms which refer more immediately to the seat and pathology of the disease; and many of the modifications will be thus found to contra-indicate oftener than they "indicate the necessity of bleeding." Nevertheless, the foregoing remark, however accidental it may have been, is probably true in a universal sense, for it is a summary principle founded

upon all the circumstances of individual cases of disease.

Looking, therefore, at the fluctuations of the pulse according to the seat, nature, force, and duration of the disease, it becomes evident that this universal symptom, as a quide to bloodletting, involves a critical inquiry into all the circumstances of disease that can modify the action of the heart and bloodvessels, and from which it appears that it must be very generally these combined circumstances in connection with the state of the pulse, and oftener the former more than the latter, which must determine the propriety of bloodletting, and "the time and the quantity" (see Index II., Pulse). The pulse, at best, as I have endeavored to show, informs us only of the nature of reflected nervous influences that are propagated upon the heart and arteries by all diseases except the cardiac, as, also, by the action of remedial agents, by mental emotions, etc. (§ 500 m, and references there, $687\frac{1}{2}$ -688). The pulse, therefore, in the foregoing acceptation, may be regarded as the sum of all the symptoms, but that its true or exact import can never be known without a reference to those symptoms. Nevertheless, the multitude consider only the state of the pulse and "debility," without any regard to their causes; or, rather, the former has now-adays lost all its significance, and "debility," representing universal pathology, directs the hand of the practitioner (§ 887). This will be manifest on considering the stimulating treatment of those diseases which are attended by a hard and incompressible pulse (§ 688 d-f), such as pneumonia, enteritis, phrenitis, phthisis, etc.

^{*} The pulse and muscular strength are in no respect guides. Both are apt to be prostrated by the attendant abdominal congestion (§ 689 t, 801, 961, p. 350, note).

NOTE MM.—DEATH-RATE IN THE CITY OF NEW YORK, AND ITS CAUSES.

In preceding editions of this work (p. 872, 1115) I have presented the statistics of mortality in the City of New York from inflammation of the lungs, bronchitis, croup, and consumption, during the months of January, February, March, and April for the years 1860, '61, '62, for the purpose of showing the results of the substitution of the stimulating for the antiphlogistic treatment, and that the "excessive death-rate" in this city is not owing to climate (than which there is no city more exempt from discase), nor to any temporary insalubrity of the atmosphere; and with the same intention I shall now record the statistics for the same months in the years 1863, '64.

In 1863, the total number of deaths during the foregoing months was 7741, of which 636 are reported as Inflammation of the Lungs; Bronchitis, 185; Croup, 383; Consumption, 1205; or nearly 1 in 12 from Pneumonia, 1 in 20 from Croup, and 1 in 6 from Consumption. The ratio of deaths from the four diseases to the

total number of deaths from all causes is about as 1 to 31/4.

In the year 1864, the total number of deaths during the same four months was 8493, of which 839 were from Inflammation of the Lungs; Bronchitis, 164; Croup, 352; Consumption, 1260; or nearly 1 in 10 from Pneumonia, 1 in 24 from Croup, and 1 in 64 from Consumption. The ratio of deaths from the four diseases

to the total number of deaths from all causes is about as 1 to $3\frac{1}{4}$.*

It is thus seen that there has been nearly the same mortality from the four inflammatory diseases during the first four months of the five consecutive years. I shall make no farther comments upon this mortality, nor upon the practice which is greatly responsible for it; but it may be worth while to show the death-rate from consumption for entire years, which for the last five is as follows: In the year 1859, the total number of deaths from all causes was 21,645, of which the rate from Consumption was about as 1 to $6\frac{2}{3}$; in 1860, total deaths 22,710, rate from Consumption about as 1 to $7\frac{1}{3}$; in 1862, total deaths 21,241, rate from Consumption about as 1 to $6\frac{2}{3}$; in 1863, total deaths 25,196, rate from Consumption about as 1 to $6\frac{2}{3}$.—See Note F, p. 1114.

The statistics have been obtained from the able and elaborate reports of Cyrus Ramsay, M.D., LL.B.. Registrar of Records and Statistics in the City Inspector's

Department.

NOTE NN.-NARCOTICS AND SENSO-PARALYSANTS AS TO PAIN.

A characteristic and practical distinction between the groups of Narcotics and Senso-Paralysants, according to the nature of the agents which I have assigned to those groups respectively, in my work upon Therapeutics and Materia Medica (§ 891, 1057 d), and upon which, particularly, the groups are founded, is, that the Narcotics exert their most characteristic effects upon the organs of organic life, while the Senso-Paralysants are felt mainly in the organs of animal life. This is remarkably true of pain, for the relief of which in the great organs of life, so far as it respects the nervous agents, we are mostly limited to opium, hyoseyamus, and conium, which are nearly useless in neuralgia and other painful affections of the organs of animal life, while it is in these conditions, and not in painful affections in organic life, that aconite, veratria, belladonna, delphinia, and stramonium display their anodyne virtue. They exert no soporific effect in their ordinary doses, and when such doses are followed by sleep it is owing to the removal of pain.

NOTE OO.—RELATIVE LIABILITY OF MASTER AND SLAVE TO PESTILENTIAL DISEASE.—MORE ABOUT ANIMAL HEAT.

When speaking of the subordinate predisposing causes of disease which increase the susceptibility of the system to be acted upon by the essential ones in cases of epidemics, and which, also, add to the intensity of disease, I attributed the comparative exemption of the Negro from the epidemic fevers of the Southern States to his abstinence from stimulating food and stimulating liquors (INDEX II., art. Acclimation, 3d subdivision; also § 630 e, 663, 814, 816 b, 827 e, 883 b); and it is now my purpose to simply state the habits of the Negro in that respect, as represented by a

*We learn from Bellever Hospital (N. Y.), that in the treatment of Pneumonia "the olden methods of sanguineous depletion with antimonials have been swept away by the advance of medical science."—Am. Med. Times, 1864. Note E. e. as to the "advance of modern pathology," and § 5].

distinguished observer who had resided several years in their midst, and whose husband was the wealthy proprietor of a large plantation. This information is derived from a "Journal of Residence on a Georgian Plantation," by Fanny E. Kemble (then Mrs. P. Butler), in which it is said that "the slaves labor hard all day upon two meals of Indian corn, or hominy, as it is called, as the regulation on this plantation, and our Negroes are generally considered well off. They go to the fields at day-break, carrying with them their allowance for the day, which is caten at noon; and their second meal is at night, after their labor is over—having worked, at the very least, six hours without intermission of rest or refreshment since their noonday meal."

The foregoing statement associates itself with what has been said in this work upon the connection of food with animal héat, as in sections 441 c, 1048-1050; and it is also an evidence of the fallacy of a prevailing opinion that a spare diet is productive of disease, and incompatible with laborious pursuits (§ 1048). I will add that this last subject is fully examined in the Medical and Physiological Commentaries,

vol. ii., p. 691-698, in an article upon "Fasting."

NOTE PP.—THE DEVELOPMENTAL HYPOTHESIS.—THE DARWINIAN ORIGIN OF SPECIES.—"MEN AND MONKEYS."

The doctrine of the origin of species by transmutation, in all the aspects of that hypothesis, is abundantly refuted as to man by the distinctions which I have indicated between the Soul and Instinct (p. 892-906, § 1078); for, however great may be the coincidences between the organization and the functions of man and animals, there is none between absolute reason and instinct. The former, as I have shown, is peculiar to man. But, if there were any just foundation for the developmental doctrine, the manifestations of reason should not begin abruptly with man, but should observe some degree, at least, of correspondence with the physical conditions. And since, also, man is completely an animal in organization and functions, the ground which is thus obtained may be carried analogically throughout the animal kingdom.

Lest an advantage be taken of what has been said of the modification of Instinct in metamorphic animals (§ 1078 p), by applying the principle to the development of the rational faculties of man in his supposed evolution from the monkey tribe, it may be said, notwithstanding the obvious want of all analogy, that the mutations of organization in the metamorphic animals are of the most fundamental nature, while the corresponding modifications of instinct are always in strict conformity with the great general plan of instinct, and farther, also, that in all these cases the several mutations of structure and instinct are progressive stages of the same individual from the germ to its full maturity. Instinct, as I have shown in this work, is constituted throughout all the animal tribes with a sole reference to the uses of the body, and that no animal has been known to manifest any of the phenomena of reason that

can not be resolved by the philosophy which I have predicated of instinct.

Glancing more particularly at the most novel of the repudiations of Creative Power, and which has taken captive so many of the scientific world, it appears to be encumbered with greater fallacies than any of its kindred doctrines. Besides the many obvious considerations of a physiological nature that apply to Darwin's "origin of species by natural selection" (p. 814, note), it is worth saying, that as all the assumed developments, or mutations of species as called by Darwin, start, at the best, with the infancy of animals (§ 1085), an objection which I alleged against the doctrine of spontaneity of beings in the work upon the "Soul and Instinct" (p. 158-165) is equally applicable to the Darwinian origin of species. The argument proceeds thus: Now let us see how far the statements of Holy Writ agree with what is manifestly fundamental in Nature. We are told, for example, that man and beast were created entire out of the earth; but had it been said that the materials of the earth organized themselves into living beings, or even that the materials were peculiar to living beings (an assumption highly probable, unless the composition had been revealed), the Narrative would be rejected by all as an imposture. Nay more, had it been affirmed that man was created in the condition of an infant, and thus left to grow up to maturity under the laws which govern his organization, without maternal sustenance and protection, without a ray of instinct, destitute of volition and muscular power, the personification of helplessness, the statement would be universally pronounced absurd. Yet is this doctrine extensively propagated through the delusion that "the Creator endowed certain forms of inorganic matter with the properties requisite to enable them to combine, at a fitting season, into the human organism" (§ 350} at p.187, 189, § 1083). What I have thus said as to the absolute exigencies of man in early life is as applicable to all mammiferous animals, and to all unfledged birds, in respect to the nature of their early food, who would, of course, immediately perish without the sustenance afforded by the parent. - Essay on the

Soul and Instinct, p. 159, 160 .- See argument in Note p. 815.

If it be objected by the advocates of Darwin's assumptions that the parent of the newly-developed species would have been the nursing mother, it will be readily seen that no animal, however much it may approximate man in organization, is in the least qualified to take charge of the human infant; a fact which may be applied, analogically, with equal force to the whole tribe of mammiferous animals, since, if it can be shown that man is an exception to any of the interpretations of nature that aspire at the origin of living beings the entire hypothesis necessarily falls.

In looking around for the species of animal out of which the human race has been developed, according to the scheme before us, that which approximates man most nearly in organization must enjoy the distinguished honor of paternity—the gorilla, orang-outang, or some one of the monkey tribe. It is considered that organization in these instances is so close upon that of man as to supply in this abstract sense a plausible pretense for a still closer relationship (§ 350\frac{3}{k}\hat{k}); and it follows, therefore, by the analogies of Nature, as well as by the law of inheritance, which is so justly argued by Darwin as the basis of his doctrine, that reason, the grand characteristic of the human race, should have also made some approximation in the gorilla or chimpanzee toward that divine attribute of man. But I have endeavored to demonstrate, in the article in this work upon the Physiology of the Soul and Instinct (p. 893-911), that no animal evinces that endowment, and that the whole tribe of apes, monkeys, and chimpanzees are vastly less provided with instinct than the honey-bee (p. 896-898, \S 1078 d, e), while man dwindles into insignificance by the side of the orang-outang in respect to the instinctive principle (§ 1078 q, etc.). However great, therefore, may be the coincidences between the organization of man and the quadrumanous tribes, it is impossible to evade the fundamental distinction which is established by reason and instinct. But even in respect to organization there are some things which concur with reason in enforcing the conclusions to which it conducts Man, for example, walks erect; but that would not be sufficiently characteristic to prove the distinct and independent nature of his being. The absence, however, of all correspondence in the uses of his upper and lower extremities, while in the quadrumanous tribes they subserve the same purposes, does estrange them fundamentally from each other; and this argument is vastly increased by the fact that the arms of the human species are intended to fulfill the promptings of Reason, while the fore legs of the quadrumana are no more tributary to Instinct than the posterior legs-both of which are properly legs.

Nor will I leave this important subject till I array another argument against the so called "typical system" of development, and which will be seen, also, to operate against the Darwinian assumptions. It is this: The differences which occur between extinct and living animals and plants do not relate to organization as it respects the life of the being, but only to certain details in the form of organs. This difference does not involve, in the least, any difference in the plan of organization, which is exactly the same in the earliest of the lowest and highest order of beings, and throughout all the intermediate gradations in the ascending series, as at the present day. Composition, germs, growth, and reproduction are, also, common to all. Organic life, therefore, has always been precisely the same throughout every link of the vast chain, and the physical agents of life, therefore, always the same (\S 632 b). Hence it is evident that the whole typical system of theoretical geology, which is founded, not upon differences in the plan of organization, but upon the form of organs, is one of the greatest fallacies that has crept into science. Nor, indeed, could this speculation have pervaded the works of geologists any more than the recent novelties of Darwin, Huxley, etc., had any one of the numerous projectors been duly informed upon the science of Physiology. Anatomy supplies no foundation for this reasoning (§ 131, 1078 e); but, on the contrary, when associated with the physiological laws which it is designed to subserve, it is opposed to their conclusions (INDEX I., article

Design).

The various attempts of arranging man in an order by himself upon the basis of physical characteristics appear to be open to objections; nor is this at all remarkable, considering the near affinities between the structure and physiological characteristics of man and certain other mammalia. The distinction founded by Professor Owen upon certain supposed peculiarities of the human brain would establish only a specific

difference. But even this has been controverted by Professor Huxley, who finally propounds the question, "Are we justified in classifying men and monkeys together? The comparison," he continues, "of the human skeleton with that of the gorilla, an orang, a chimpanzee, or any of the higher apes, will answer the question, and show at a glance the great resemblance and similarity there is between them (§ 1078 e). Now the gorilla, for example, is admittedly placed in the same order as the lemur, the cheiromys, and the galeopitheus, which differ far more from it than it does from man. Thus we can not but place them in the same order, or

else all our notions of affinities and resemblances fall to the ground."

This presentation of the subject is plausible, and such as is anticipated in § 1078 e. It is at best, however, an artificial grouping of animals, without showing in the least that those which approach nearest in structure are not as perfectly distinct species as are the orang and the honey-bee, and not more allied to each other in their origin. But a common fallacy has beset all the attempts to establish man as a special order, under the artificial arrangement, that of neglecting the great facts which distinguish him essentially from every animal-his endowment with reason and his deficiency in instinct. Even the systematists, who have indicated peculiarities in the cerebral structure of man, have left the impression that reason depends upon those peculiarities. It is the error of materialism. But if the demonstration which has been made in this work of the substantive existence and self-acting nature of the soul and of the instinctive principle be true to Nature, it may be safely said that reason alone places man in an order by himself, whatever may be "our notions of affinities and resem-

blances" among skeletons (§ 241 c, note, 1078 d, e, q, Note C). Finally, an argument against the hypotheses which ascribe the origin of species to blind material forces, and sufficiently conclusive as to man with all who believe in his immortality, may be founded upon that single fact, which so completely distinguishes him from the animal tribes. The same philosophy must obtain here as in all the suppositive conclusions of a physical nature, and it must be equally true that the soul of man not only originated, but became rational and immortal under the influence of those natural forces and laws which are supposed to have given origin to his material body—whether it have been according to the doctrine of Carpenter, Mülder, Tiedemann, etc. (§ $350\frac{2}{3}$ f, l, m), or as expounded by Professor Lewis (§ 1085, p. 922), or by the late projector, Darwin (p. 814, note). The first of these doctrines supposes that the elements of matter united into living beings in virtue of the forces with which they are endowed, and therefore, by parity of reason, the immortal soul of man must have had the same origin. If Creative Power be invoked for this particular difficulty, the physical structure and its life must fall under the same rule. There is no greater evidence of the existence of "vital properties in the elements of matter" than of the soul or instinct. But it is enough that the materialistic doctrine excludes all direct agency of Creative Power, and consigns the whole work to second causes. If that Power be allowed to have had any creative action in the production of organic beings, there can be no compromise with the hypothesis of second causes as it respects other parts of the same beings. While the Creator was employed about the immortal soul, it must be allowed that He would have equally attended to the no less difficult organization. A similar philosophy must apply, also, to the "parturitive" hypothesis (p. 922). And coming to Darwin's scheme of slowly progressive mutations, it is necessary that the animals in the advancing series out of which man was developed should have possessed not only a rational soul closely allied to man's, but that soul should be immortal. This unavoidable conclusion carries us back through all the ascending series of animals till we reach the "primordial cell" (§ 1051), or Darwin's "primordial form," for there alone can we look for the beginning of an *immortal* soul, according to the doctrine of the "origin of species by natural selection." How that cell or that soul came into being we are left in ignorance, as in the case of Tiedemann's "organic matter" (§ 3503 l, p. 188). But if an immortal soul were not inherent in the cell, or at least in some animal anterior to man, it must have been a supernatural endowment of the human race, or, in other words, a special act of Creative Power, and therefore, also, by an irresistible logic, man's physical structure was equally a direct act of the same This conclusion, it is true, requires the admission of man's spiritual immortality; and if it be objected to this that man is not thus distinguished from animals, I recur to my argument in proof of the perpetuity of the former and the extinction of the latter (§ 1079 a). But I do not consent to the exclusion of well-established Revelation from matters of science, and I therefore contend that the mission of Christ determines the resurrection exclusively in favor of rational and responsible beings.

Since, therefore, it appears from our premises that the soul of man is so contradistinguished from the instinct of animals that it can have had no relation to the animal tribes, and that it follows, as a consequence, that man's physical organization was equally a direct act of Creative Power, and since, also, by common consent, he is on common ground with animals in his organization, it equally follows that the origin of every distinct species of animal was a special act of the same Power.

NOTE Qo.—HIGH ANTIQUITY OF THE HUMAN RACE.

Although this is not the place to discuss the question which has been much agitated of late among scientific men as to the high antiquity of the human race, or the proper interpretation or authenticity of the Mosaic narrative of creation, and other kindred topics, but to which, for special reasons, the author has adverted in this work (§ 14 c, 250\frac{3}{2}, 632, 1051, 1079 b, 1083, p. 922-928, \frac{5}{2} 1085), he is led to repeat an objection which he alleged in his "Theoretical Geology" (\frac{5}{2} 1079 b) against the supposed antiquity. The objection consists in the physiological fact that the human mind was alike endowed in the remotest past as at the present day, and is constitutionally so progressive that as soon as the race in any given locality exceeded in numbers the natural means of subsistence, they should have addicted themselves to the culture of the earth and other useful arts, and there should have thus descended to us from those early stages of society materials at least as advanced as those through which alone we learn the former existence of a vast population in the Western world. They should be also incomparably more abundant, since in the case of the geological man he is supposed to have been multiplying through hundreds of thousands of years; while the origin of the monumental vestiges of the race, of an unequivocal nature, lies within the compass of four thousand years, and the testimonials that have been recently produced in support of geological periods are insignificant in amount, and can not be shown to be of an earlier date than the Chaldean and Egyptian Architecture. Human reason, under equal circumstances, was as creative at its earliest dawn as at any later period, and the multiplication of mankind, according to the nature of climate and the progress of art, went on then as now. Science had not dawned when David, Solomon, Isaiah, and Homer wrote, and no better thinkers and writers have since appeared. Greece and Rome perfected History, Architecture, Oratory, Sculpture, Painting, soon afterward, and two thousand years more brings us to our own times. If, therefore, so much has been accomplished within the four thousand years beyond which we can not ascend, and such a host of brilliant minds contributed to the earliest page of history, what, I say, would not this same creative mind have produced had it been in operation ten thousand years before the structures, and sculptures, and writings of Babylon, Nineveh, and Egypt? It is now too late for the afterthought that the human mind has been subject to changes since the law of "natural selection," or any "law" within the compass of imagination, produced the physical organization of the race; and, moreover, what is known of the unvarying nature of Instinct in all species of animals determines the same stability for human Reason.

NOTE RR.-LONG SENTENCES.

A sentence which occurs in section 638 has been very justly regarded as a "long one." Indeed, the Author concedes that it may require more than one sitting to read it through intelligibly. Its design may not be obvious to many, although it carries its own interpretation in showing the intimate relationship of the various topics involved, and which had been antecedently presented as the fabric of physiological medicine. That a system so complex and multifarious in its constituent parts, embracing the entire field of physiology and its applications to Pathology and Therapeutics, should be susceptible of exposition in a continuous sentence without violating the unity and harmony of a consistent whole, must be received as an evidence of the realities of its subject. But what has been now said is more particularly intended as a commentary upon the "long sentences" which abound in the Second Index, and which will be seen to embrace a variety analogous to the characteristic of section 638. The common nature of the subjects, under each article, brought them together into compact and continuous sentences, while, also, this congruity illustrates and confirms the harmonious system which is indicated in the first paragraph of these Institutes.

INSTITUTES OF MEDICINE.

BY MARTYN PAINE, A.M., M.D., LL.D.,

Professor of the Institutes of Medicine and Materia Medica in the University of New York; Author of the "Medical and Physiological Commentaries," "A Treatise on the Soul and Instinct," "Therapeutics and Materia Medica," etc., etc.; Corresponding Member of the Royal Verein für Heilkunde in Preussen; Corresponding Member of the Royal Medico-Chirurgical Academy of Turin; Corresponding Member of the Gesellschaft für Natur und Heilkunde zu Dresden; Honorary Member of the Imperial University Physico-Medical Society of Moscow; Member of the Medical Society of Leipsic; of the Medical Society of Sweden; of the Montreal Natural History Society; and of many other Learned Societies.

With a Portrait. New Edition, Revised and Enlarged, with a Copious Index.

The Publishers, in offering to the profession a New and Enlarged Edition of Dr. Paine's Institutes of Medical Press in behalf of the work, and subjoin numerous extracts from late periodicals. Some of the extracts bear upon a controverted question, but the Publishers are not disposed that their copyright shall suffer by any abstraction from the merits of the work; and that the latter may go forth under unquestionable authority, they have made the extracts of unusual length. As a prophet, also, is said to be without honor in his own country, the Publishers are disposed to show that exceptions occasionally arise, and that this may be the more apparent, and as they are content withal, they limit the extracts to American periodicals; or, rather, do not await the arrival of Foreign Notices of this Fourth Edition of the Institutes.

October 8, 1853.

From the New York Journal of Medicine, May, 1858.

"The Institutes is full of learning and philosophy, and the reader, while impressed with the profound crudition of the author, can not but be amazed at the amount of labor the book discloses." Professor Paine is engaged in a struggle for truth. His mind is concentrated upon the elimination of facts, and in the pursuit of what he deems right he seeks not the applause of his contemporaries. He knows full well that principles must and will survive the disputations of the controversialist. "He is, in every sense of the word, a medical philosopher, a devotee of science, and a commentator whose opinions will not only pass to posterity, but receive the high tribute to which they are entitled. Inflexible in his convictions of truth, he can not be moved by friend or foe—and he pursues his onward course with an earnestness and zeal characteristic of the man. " We can confidently recommend the In-

stitutes both to the practitioner and student of medicine; to the former it will be a rich treat—it will open to him the wide and fruitful field of medical science, and he will see elaborated in it the great and leading questions which have so long constituted the basis of controversy among the learned in our profession. The latter will find it a treasury of knowledge—a veritable encyclopædia—full of the prominent facts of his science; and its tendency, moreover, will be to induct him into habits of thought and reflection. Lastly, we may be permitted to say that the article on the 'Rights of Authors' has been elicited by what Professor Paine deemed an infringement upon his claims; and he has entered upon the subject not only with zeal, but, in the language of the law, he has made out his case by a chain of very positive evidence."

From the same Journal of July, 1858.

"There is no where to be found in medical literature, nor in all medical works extant put together, so full, so complete, so accurate an exposition and elucidation of the functions, and the paramount importance of the ganglionic system in influencing all the organic functions (including secretion) physiologically and pathologically, as is contained in the 'Institues' and other writings of Dr. Paine. An examination of the Index of the 'Institutes' alone will prove this. Fifty such essays as that of Dr. Campbell could be compiled from the 'Institutes,' and the leave material, facts, and illustrations enough for as many more, all embodying and setting forth

the same doctrines. ** The author of the 'Institutes' and of the 'Medical and Physiological Commentaries' can well afford to bide his time. His fame is secure. It will grow brighter with time. The profession will delight to cherish it and to do him honor. They will not allow a single particle of his just merits to perish, or to eappropriated by others. Posterity will vindicate all his just claims and assign his rank among the great minds of our country. But few properly appreciate, or are even acquainted with the extent of his Herculean labors. None but those who have labored in the same field can justly estimate the vast range of his learning.—C. A. L."

From the American Medical Gazette, New York, June, 1858.

"That the 'Institutes of Medicine' and the 'Medical and Physiological Commentaries' are characterized by great analytic power, profound philosophy, rare genius, and unsurpassed learning, no candid reader can deny; that they will rank with the foremost works in our science, and 'endez, as it contains entitle their author to a high rank among the

greatest men in medicine, will hardly be disputed. * In the late Appendix to the Institutes many important subjects are discussed with the usual acuteness and ability of the author. The Index, of 175 pages, may well be called a model index, as it contains a brief summary, as it were, of the entire work."

The September Number of the foregoing journal contains a forcible and triumphant article of thirteen pages, by Professor C. A. Lee, in defense of Professor Paine's claims of originality in elucidating and applying what is designated as the "excito-secretory function of the nervous system," and showing that the term itself has been derived from his Institutes of Medicine. We

quote the following:

"Dr. Paine claims, and very justly, as may be seen by our extracts, a long priority in designating the nervous mechanism through which the secretions are physiologically influenced; and although he has not thought it worth his white the insist more his avisity in the small matter of to insist upon his priority in the small matter of bestowing a name upon the function, we have shown that he suggested the very name which is now apparently conceded by nearly all the mednow apparently conceded by nearly all the medical periodicals in this country to form the only originality belonging to Dr. Campbell. But what is alone of any importance, Dr. Paine was not only the first, but still the only one to carry the 'excito-secretory function' and all the physiological laws of the nervous system into pathology and therapeutics. * But Dr. Paine regards the excito-secretory function of the nervous system as a very minor part of the influences of that tem as a very minor part of the influences of that system, the most important of which is its variously alterative effects upon the organic func-tions; or, in his own language, 'in all the cases the nervous power is rendered stimulant, or de-pressant, or alterative to the organic properties presam, or attentive to the organic properties and functions, and variously energetic, according to the operating cause, and the intensity and suddenness with which it may operate."—p. 107. "The whole of this disputation has had its origin "The whole of this disputation has had its origin in a mere pretense that has grown out of a name. Excito-secretory function is the magic word which is made to engulph the whole philosophy that concerns the labyrinth of the organic functions in their connection with the nervous system. But it is a word of such partial import as not to convey the slightest connection with pathology and therapeutics: but, on the contrary to im. and therapeutics; but, on the contrary, to impress the belief that it is limited to the natural state of the body. It disregards all the modifying influences of the nervous system upon organing innences of the nervolus system upon organic actions and their products, whether induced by remedial or morbific agents; and the inappropriateness of the term, beyond its mere physical given in the second of the pathers of the pathers. ological or therapeutical branches of Dr. Paine's Institutes of Medicine.

From the Virginia Medical Journal, July, 1858.

"In these degenerate days, when all men bow to In these degenerate days, when air men bow to the sway of public opinion, and are more prone, alas, to be ruled by policy than to follow the guidance of reason and judgment; in these latter days.—when the voice of the people is the voice of God, we, at least, should not withhold our praise from him who fears not to stem the current of popular opinion, and who strikes a bold blow in defense of the right. However we may wonder at his hardihood, and hesitate to follow his rash example, we involuntarily admire this uncompromising devotion to his own doctrines, and respect the courage we are too timid to imitate. The author of the work we have now under consideration is emphatically such a man as der consideration is emphatically such a man as we have endeavored to describe. At a period in the history of medicine when the mind of the profession is running like a torrent under the guidance of Andral, Louis, and the other brilliant leaders of the pathological anatomists, into the humoral theory of disease—when, too, the reaction against the heroic school of medicine had reached to such an extent as to favor the rice and tamperary success of the infinitesimal rise and temporary success of the infinitesimal dogma, and, more important than all-when the dogma, and, more important than all when the progress of organic chemistry is startling the minds of men with its bold innovations and brilliant theories in physiology and pathology, it was then that Dr. Martyn Paine, almost alone, with nothing to support him save his indomitable energy, his great learning, and his intrepid heart, stood up before the medical world in defense of the waning school of vital physiologists and the time-honored solidism of Stahl and Hunter-

when medicine expectanté was most triumphant when mentaine expectant was most triumpiant he still advocated blood-letting and the administration of remedies on the heroic plan—when Liebig, Thompson, and Lehmann unite in leading the student through the attractive investigations and plausible theories of zoochemistry. Dr. Paine still gallantly defends the creed of Bichat and the vitalists against all comers, and charges boldly and effectively upon the ever increasing ranks of the humoral pathologists.

"It is justly due to this learned and zealous investigator and medical philosopher to say that we do not believe there can be found another man in America who would have waged this unequal war for so long a time and with such signal ability; and although we doubt whether many of our readers have ever devoted time enough to our readers have ever devoted time enough to his various books, tracts and essays to enable him to do justice to his labors in medicine, yet we will point to every thing which has emanated from his pen as being characterized with an amount of learning, profound reasoning, and a power of resistance equal to the emergency. ** We can not but be astonished at the amount of ground traveled over by this zealous student, and we may point him out to the young in the profession as a noble example of what may be ac-

The August Number of the foregoing journal contains the able article to which reference is made under our extract from the New Hampshire Journal of Majains.

shire Journal of Medicine.

From the American Journal of the Medical Sciences, Philadelphia, July, 1858.

"Dr. Paine's Institutes of Medicine presents throughout ample evidence of medicine presents throughout ample evidence of the general erudition of its author, his habits of close investigation, and his intimate acquaintance with the subjects of which he treats, and with the views entertained by others in respect to them. A degree of originality and independence of thought pervades all his teachings, whether these have reference to the vital conditions and functions of the human organism, the laws by which they are governed, or to the nature, causes, and tendencies of disease, and the curative measures by the agency of which this may be best conducted to a favorable termination.

"The Institutes of Medicine as presented by Dr.

Paine, whether we receive them as true, or reject them as talse, are, nevertheless, based upon a

truly philosophical investigation, aided by all the accumulated light derived from the observations, experiments, and reasoning of preceding and contemporary authorities, of the physiology, pathology, and therapeutics of the human sub-

It is, we confess, somewhat cheering to meet It is, we confess, somewhat cheering to meet with one of the high intellectual endowments of Dr. Paine, who, at the present day, when the doctrines of physiologists, pathologists, and therapeutists are alike verging into materialism—when the organic functions, at least, of the animal organism are all referred to a mere modification of the same action and reaction action and reaction and reaction action and reaction and reaction and reaction and reaction action action and reaction action action action and reaction action actio cation of the same action and reaction which oc-cur in brute matter, has sufficient courage to raise his voice in defense of the vitality of the system; in recognition of the fact that our organs are built up and maintained in a healthful ; gans are built up and maintained in a heatoning condition for the regular performance of their appropriate functions by a principle which we denominate life, and by which the material elements of the animal organism are almost entirely removed from out the control of those merely physical laws to which, as dead matter, they would necessarily be subjected.

"We consider the treatise to be one well worthy of an attentive study on the part of every advanced student and practitioner of medicine, to whose notice we earnestly recommend it. Although far from being inclined to indorse the accuracy of every doctrine advanced by the author, nor the chain of reasoning by which he attempts |

its support, we are, nevertheless, convinced that his prelections, from the amount of truth set forth in them, and the vitality by which they are pervaded, if they do not actually convey sound views on every thing that relates to the philosophy of medicine, can not fail to lead at least to a correct basis for the establishment of such views. The strong conservative predilections of Dr. Paine, which induce him to subject every new observation and theory in medicine to the severest scrutiny, and to refuse its admission until positively established, can have no other than a favorable influence upon his readers, by teaching them to be progressive only in the road of positive truth. -D. F. C."

From the North American Medico-Chirurgical Review, September, 1858.

"No one can read the Institutes of Medicine without being filled with respect and even admiration for the profound erudition, the painstaking and systematic research, and the laborious reflection exhibited so abundantly in its pages. With careful and discriminating hands Dr. Paine thas gathered together, from the writings of both the earlier and contemporary physiologists, the numerous important facts and details which constitute the subject-matter-the crude materialso to speak, of his favorite science, and arranged and built them up into a stately edifice—the In-stitutiones Medicine—whose great corner-stones

are Physiology, Pathology, and Therapeutics. We conclude our remarks by earnestly recomending his work to the careful perusal and study of every one interested in physiology, whether in its aspect of a pure or an applied sc The breadth and comprehensiveness of many of its doctrines, the great questions in which it abounds, and the consummate skill and learn-ing with which these are generally treated, stamp it as a valuable treatise which should find a place in every philosophical library and be consulted by every physician who practices his profession as a science and not as an empyrical art.

From the Medical and Surgical Reporter, Philadelphia, May, 1858.

"Dr. Paine gives us two very copious Indexes and an Appendix to his Institutes of Medicine, and we find throughout the work constant referand we find throughout the work constant reter-ences from page to page to facilitate the task of the student in acquiring a complete knowledge of every subject. Finally, as a postscript, he de-tails in full what he claims as his own, and we think we can not do better than lay his claims before our readers.

"In his Preface to this fourth edition Dr. Paine says: 'This work, originally published in 1847, remains without change, as the author has seen no reason to modify any of his doctrines.' But in his Appendix he does ample justice to all subsequent discoveries in physiology and chemistry. He says: 'Whatever may have been subsequently disclosed in physiology and chemistry is essentially in harmony with all that the author incorporated in the foundation upon which his Institutes are erected, and places them beyond the probability of being much invalidated. In his discussion of organic chemistry as applied to physiology, pathology, and therapeutics, it is evident that he could not doubt that this invasion upon medicine would recover appearance. sica upon medicine would prove ephemeral, and that the chemist would soon retreat into the ap-

that the chemist would soon reteat into the ap-propriate field of nature."

"He reviews very thoroughly all the evidence connected with this statement, and certainly shows good logical reasons for his views."

From the Charleston (S. C.) Medical Journal and Review, July, 1858.

"Few men have labored more constantly, more earnestly, and with more singleness of purpose than the venerable and learned author whose late edition of the Institutes of Medicine now lies be-fore us. * * The arrangement of the work is exstep the reader is led on from the study of the step the reader is led on from the study of the functions as they exist in health to the causes and consequences of their derangement, and to the methods of treatment adapted to them.

"Professor Paine's style is at once vigorous, bold, and classical. Stating in few words the thought which he would convey, he does so in

such a manner as not to allow it soon to be effaced. His writings are every where characterized by perspicuity and terseness; and if his meaning is not understood (as may often hap-pen) it is not due to the faulty expression of it, but to the fact that he deals with subjects of great depth and difficulty of comprehension-beyond depth and difficulty of comprehension—beyond the span of many minds, above the reach of all, unless close attention and undeviating thought be given to their study. The reader may at first find some difficulty in following the writer, but he will soon become accustomed to his style, and read with interest and facility."

From the Boston Medical and Surgical Journal, May, 1858.

"One can not fail, in reading Dr. Paine's Institutes of Medicine, to be struck with the immense industry of the author, with his originality, and with his consistency; and if we must differ from him in some of his views, we do so with the diffidence due to a learned and conscientious teacher."
In a subsequent Number (July 29th) it is said by "W. E. C." of Dr. Paine's Medical and Physiological Commentaries:
"The first neculiarity of Dr. Paine that arrests

"The first peculiarity of Dr. Paine that arrests us is the solid, methodical manner in which he plants himself at his work—the thorough à plomb which he establishes for himself before he grapples with his subject-matter. You feel assured of this in the first ten lines you read. It is not going to be any trifling affair, you are at once

convinced. It is a brawny student of the old very old sort you have got into companionship with, and if you wish to keep his company you must buckle yourself closely to the matter before

you, and set yourself to hard work.
"The scope he has taken is our next point of note. This is not only shown by allusions and casual references in the text, but the foot of almost every page in the book has quotations, with chapter and page, from apparently every work that can possibly illustrate the subject or enforce the writer's views, including not only accredited books, magazines, and monographs in our pro-fession, but those from every walk of literature, giving us a high opinion of the author's cultivation of pursuits too often neglected by medical men. These are used, too, not, as is often the case, simply to set off the text and suggest ideas of the research of the writer, but as genuine illustrations either of the matter in hand and the peculiar view of it taken by the writer, or of the mental temperament of the time in which the doctrine or its converse was first propounded. In short, the book is not that of a sciolist, by a great deal, but of a thorough and strong scholar, from a very contact with whom strength and refreshment may be derived, even if difference of opinion should exist and remain after it.
"As we have said, it is impossible to review

here such a work as Dr. Paine's, but we may give an idea of some of its contents, &c., &c

A Dissertation on the Hippocratic and Anatomical Schools, and another on the writings of Louis, conclude the second volume. The last paper is as remarkable and as characteristic as any thing in the two volumes; of and in itself it shows fully the scope, power, and variety of the scholarly Author. We will not comment upon scholarly Author. We will not comment upon it, but earnestly recommend a perusal of it, and in return for our good advice would only like to watch the countenances of certain friends of ours well engaged in the recreation."

From the Montreal Medical Chronicle, September, 1858.

"No one can peruse these volumes of Dr. Paine (the Institutes and Commentaries) without being forcibly impressed with the vast amount of erudition displayed by the learned Author. dinon displayed by the learned Author. Every page bears witness to an extent of reading and research really surprising. It is not only the standard medical works in various languages that he has consulted, but periodical literature has been thoroughly ransacked to discover new thoughts, truths, and experiments in support of and bearing upon the peculiar views he advances.

"As we agree in the main with the vitalists, although differing from them in some respects, and as we admit the vast importance of much that is tanght by the zoo-chemists, we shall endeavor to give our readers, in as few words as possible, the view we take of life."

From the Buffalo Medical Journal and Review, September, 1858.

"The Institutes of Medicine first saw the light at a time when the humoral and chemical doctrines of life were in the ascendancy, and when trines of life were in the ascendancy, and when vitalism was scouted as an obsolete relic of bygone ages. But now, when the opinion begins very generally to prevail, that the physical doctrines of life will not suffice for the satisfactory solution of the varied phenomena of organic beings in health and disease, nor for the explanation of the modus operandi of remedies, there is evidently a commencing reaction in favor of the doctrines of vitalism; and this work, and the dentily a commencing reaction in layor of indectrines of vitalism; and this work, and the 'Commentaries' of our author, begin to be sought for with avidity. This must be greatly gratifying to Prof. Paine, who, with far-reaching foresight, saw very clearly that a system of medical philosophy, based on the laws of the ingranic world, could not stand when brought to the test of observation and experiment. On reading the 'Institutes,' we can not but be struck with the 'institutes,' we can not but be struck with the admirable consistency of the author's views throughout the entire work. The same principles, the same philosophy form the foundation and substratum of the whole. There is no inconsistency, no contradiction, not even the shadow of any clashing throughout. Taking up each topic in its natural order, as each successive one emanates from, or depends upon, the preceding, there is a lucid order every where displayed—a chain, with no broken link. As in a mathematical demonstration, each step prepares the way, and is necessary for the succeeding. The demonstration proceeds with logical exactness and unbroken sequence, till the conclusion rests on a basis impregnable as truth itself.

As the author truly remarks, this is the first effort that has been made to present the natural relations of the whole subject of the institutes of medicine, including physiology, pathology, and therapeutics in their just order—to point out the

affinities, and to exhibit throughout the important laws and essential foundations of vitalism and to maintain throughout a consistency of facts and of laws that shall stamp the whole as the philosophy of medicine. This has been most successfully accomplished; and the zeal, learning, and genius displayed in its accomplishment will forever stamp the author as a leading spirit in our profession-as one of the great masters in our art. If the work bear something of a contro versial aspect, it was unavoidable in carrying out the great design of the writer. A simple expres-sion of facts, of experience, and of philosophical doctrines, would not have sufficed. It was necessary to expose and refute the errors with which the subject was environed.'

In an extended analysis of the work, the reviewer enters upon the author's original views of the nervous system, and more specifically as to the "excito-secretory system," showing that even the term itself was derived from writings of his as early as 1842, but that he regarded it as only a small part of the influences exerted through the same system of nerves, and quotes the author extensively to this effect. "No one," says the Reviewer, "can read Dr. Paine's Institutes with-Reviewer, "can read Dr. Paine's institutes with-out being satisfied that 'excito-secretory' is every where comprehended in what is set forth as to the general organic influences of reflex action. The grand doctrine is again and again reiterated in every part of the work, as on page 661," &c. "It is not too much to claim for our author and

countryman that, with unsurpassed acumen and ability, he has abundantly established the fact that secretion in animals is conducted by powers implanted in every part, but that it is constantly influenced physiologically, pathologically, and therapeutically, by reflex action of the nervous system."

From the Southern Medical and Surgical Journal, Augusta, Ga., August, 1853.

"Of all American writers none has been more indefatigable and laborious than Professor Paine, and the works of but few, either in this country or in Europe, display a greater amount of learning than we find enriching both the Institutes and Commentaries of this perhaps most recondite of American authors. On opening any of his works we may be said to be at once 'lost in a sea of er-udition,' and his copious references to the authors of every country and every language attest his familiarity with the general literature of the science. * In an age when Humoralism and Organic Chemistry are threatening to displace all other views of physiological and pathological ac-

tion, this work, because it is ultra in its vitalism and solidism, must exert a most salutary influence upon the history of the medical opinion of the present and the rising generation. It requires no half-way assertion of the power of nervous action to gain its admission; but he who would advocate its unmodified sway, as Dr. Paine does, must be as firm and uncompromising as he has been throughout the comprehensive work be-The present edition has been prepared, fore us. apparently with great care. A most copious an-alytical index much enhances the value of the volume, and attests well the perseverance and industry of the author."

From the Memphis Medical Recorder (Tenn.), March, 1853.

"All praise, we say, to those pathologists, with | therapeutics, it has been the distinguishing merit Professor Paine at the head of them, who so long and so ably kept alive the anticipation that it was through the reactions of various departments of the nervous organization, one on the other. that pathological and physiological sympathy resulted. ** In America no earlier or more sedu-lous laborer in this field can be pointed out, as we think, than Professor Paine; whether discussing the principles of pathology, or physiology, or

of this writer always to keep steadily before his mind the probable influence of reflex nervous action in the production of the phenomena he may be treating of. * * Especially has he acquired well-won laurels by the use he has made of this principle in the controversy with the mere chemical theories upon which the influence of Liebig was leading men to ground all explanations of vital or even mental processes."

From the Nashville Monthly Record (Tenn.), September, 1858.

After commending the Medical and Physiological Commentaries, Professor Wright remarks that:

"It is in the Institutes of Medicine that the great principles of vital physiology and pathology are broadly and systematically stated. It would be impossible for us, if we had much more space than we have, to give any thing like a satisfactory analysis of this profound and inestimable work. We will only say that if our whole system of medical philosophy has escaped being

overwhelmed by the confident dogmas of the chemical school; if we have learned to look for perverted forces rather than vitiated material in pathology; if our younger writers see more of the nerves in diseased and healthy action and less of ferments and catalyses than they did a few years ago, then he who desires to assign the palm to him who wielded the sword while there were none to stand by him, should cast a glance back at the Commentaries and Institutes of Mar-tyn Paine before pronouncing his decision."

From the Nashville Journal of Medicine and Surgery, July, 1858.

"The Institutes of Medicine, the Medical and Physiological Commentaries, and Essays on Vitality and Remedial Agents, are the titles of some of the works which have obtained for Dr. Mar-tyn Paine the well-earned name of the great New York Physiologist. The first of these is a work of no ordinary merit, filled with the marks of profound scholarship and genuine philosophy, covering the entire field of medicine, and teaching it as a harmonious whole. ** We can confidently recommend the Institutes as a treasury of learning and invaluable Cyclopædia of medi-cal knowledge, well calculated to lead the stu-dent into paths of logical instruction and habits of sound reasoning, as well as instructing him in medical science.

From the New Hampshire Journal of Medicine, July, 1858.

"It would be impossible to review this immense book in less than one hundred pages. is a monument of the learning and industry of its author, and is full of valuable facts and prof-

itable suggestions."

The August Number of the same periodical copies from the Virginia Medical Journal an able, elaborate, and thorough defense of Dr.

Paine against the misrepresentations of an Enraine against the misrepresentations of an En-glish Reviewer, with the following prefatory re-mark: "No apology is necessary for occupying our pages with this long article. The justice of the views here expressed, both in relation to Dr. Paine's works and the English reviewer will be apparent to all."

From the Atlanta (Ga.) Medical and Surgical Journal, September, 1858.

"In these works (the Institutes, Commentaries, &c.), are embodied the views of one of the ries, acc.), are emodated the views of one of the most laborious and learned medical philosophers of this or any other country upon the complicated theories in physiology, pathology, and therapeutics, in reference to the great principles and laws of organic being. * We commend their contents in the most dended manner as in the historied. in the most decided manner, as in the highest degree worthy of the most thorough investigation.
** Notwithstanding, however, our great respect
for the author of these works, we do not desire to be understood as committing ourselves to his views, being, as he is, the peculiar defender in this country, of what we conceive to be (as we understand them) the erroneous doctrines of Sol-idism and Vitalism."

From the College Journal of Medical Science, Cincinnati (O.), July, 1853.

"However much we may differ with the author upon some points, we feel that the *Institutes* contains a mine of knowledge within itself, and bears the imprint of the close student and original thinker. We think, in recommending the book to our readers, that we are conferring upon them a personal favor."

From the Oglethorpe Medical and Surgical Journal, Savannah (Ga.), June and August, 1858.

"This work enjoys celebrity among the grad-uates of the University of New York, and has been favorably received by the profession gener-could be more appropriately applied than to this

The same journal says of Dr Paine's Medical and Physiological Commentaries that "No work

could be more appropriately applied than to this production of the mind and pen of its accomplished author.

From the New Orleans Medical News and Hospital Gazette, July, 1853.

"In our last number (which we have not seen) | we noticed Professor Paine's Institutes of Medicine. We have now to make our acknowledgments of the foregoing valuable works (the Medical and Physiological Commentaries, and Essays | notice of the whole of these valuable works."

on Vitality and Modus Operandi of Remedies), which are most welcome to a place in our library

From the Peninsular Journal of Medicine and Collateral Sciences, Detroit, March, 1858.

"We bespeak for this enlarged edition of the | Institutes of Medicine a hearty reception and a studious reading."

From the Cincinnati Lancet and Observer, October, 1858.

"No name in American Medical Literature occupies a more prominent or worthy position just now than that of Professor Martyn Paine; no works have been reviewed in our medical journals which have exhibited such profound learning, such industry, such extended research. The works, whose titles are given above (The Institutes, Commentaries, and Essays on Vitality and Remedial Agents), embrace a period of almost twenty years, from their first to their last dates of publication, and the most superficial reader can not but bear witness to the singular unity of design in the entire series of works, as well as to their careful maturity, for which so few medical writers of the old or new world have labored, and to which so few arrive. This testimonial to the genius of Paine, in which the medical press of America so cordially unite, is the more memora-ble when we call to mind the obstacles which he has encountered, the elements of opposition

through which he has advanced to such honorable position. Twenty years ago the mechanical and chemical doctrines of physiology, whereby it was sought to abandon the idea of a distinct Principle of Life, were largely adopted by leading philosophers of the world; but, in the very face of those prevailing doctrines, Paine became at once, always-and always consistently-eminently the champion of vitality and solidism. These two ideas are the foundation and key-stone of all his views. He had the wise foresight to anticipate that the prevalent opinions of twenty years ago were unstable; and though slowly working his way onward and upward, his ultimate triumph has proved the highest tribute to his geuius and scholarship."

"To the laborious thinking student of medi-

To the laborious thinking student of medicine every where we commend the writings of

Martyn Paine."

From the Maine Medical and Surgical Reporter, January, 1859.

"Dr. Paine discusses (in the Institutes) with marked ability the points of difference between the vitalists, of whom he is the most distinguished exponent, and the chemical physiologists."
"The arrangement (of the subjects) is philo-

From the Peninsular and Independent Medical Journal, Detroit, Michigan, February 7, 1859.

tutes of Medicine) is not second to any one of the kind in the language, if any can be found of equal merit."

"A profound and methodical thinker and an N. D. S.

"We may safely say that this work (the Insti- | erudite philosopher, Dr. Paine has shown consummate skill in presenting his favorite and truthful theory of Vitalism, as opposed to the chemical and mechanical doctrines of life."—

From the New York Medical Press, January 22, 1859.

"This elaborate work the Institutes) displays | and distinguished author. It is, at the same in every page the profound learning, immense time, a triumplant refutation of the false docresearch, and sound philosophy, of the venerable | times of materialism, and other kindred theories."

From the Pacific Medical and Surgical Journal, San Francisco, California, December, 1858.

"Is there a science of Medicine? We think there is, but it is, like the tomb of Moses, un-known to this day." "The facts exist; but they are not acknowledged by all; they are not classi-

fied," &c.
"Our author has attempted, in these Institutes,
"Our author has attempted, in these Institutes, ceeded in giving more of the true philosophy of

| medicine than has ever before been given in any work. There is order, sequence, and harmony to an eminent degree in this work. It is an edifice, and though not an Egyptian pyramid, it is still a magnificent structure, which few men in our profession could make in greater perfection, or in more ample proportions."

From the Medical Journal of North Carolina, April, 1859.

"These are works (The Institutes of Medicine and the Med. and Physiolog. Comm.) of vast research, of the most extensive erudition, and of search, or the most extensive crudinon, and or wonderful ability, reflecting the greatest credit on their author, his country, and the profession of which he is a member. They embrace, in fact, the whole areana of medical science, containing full expositions of every department in-cluded in the professional curriculum, presenting learned and erudite treatises on all topics of interest to the physician, and offering so wide a field for contemplation and study as to fill us with surprise that one man could have accom-plished so much. There is an unpretending simplicity in his style, too, which is very pleasant and attractive, especially in these days of bombastic inflation and pedantic superfluities.

fact, Dr. Paine's works are a success, and not even the most carping critic can deny the fact without proving himself too ignorant and malicious for his office. As regards the great subjects of 'soldism,' 'humoralism,' 'vitalism,' &c., which are so extensively discussed in these books, we have neither the time nor space to consider them at present but can only say that Dr. Paine suc neither the time nor space to consider them at present, but can only say that Dr. Paine sustains his views with wonderful plausibility, erudition, and ability. No physician should esteem his library complete unfil these three admirable works have been added to it, not as a mere ornament or for the name of the thing, but to be studied carefully and continuously as well as in nament or for the name of the ining, but to be studied carefully and continuously, as well as in that spirit of exultation which the pre-eminent success of a fellow-countryman must engender in every patriotic bosom."

From the Baltimore (Md.) Journal of Medicine.

Professor E. Warren, M.D., the editor, remarks | and the special champion of those great doctrines that "Dr. Martyn Paine is, by all comparison, of Vitalism and Solidism, to the advocacy of which the most able and crudite of American authors, | we stand at all times committed."

From the Cincinnati Lancet and Observer (Ohio).

"As a work of scholarship Dr. Stille's Therapetties and Materia Medica e stainly ranks with any thing our medical authorship has produced wonderful learning, 'PAINE'S INSTITUTES.'"

NOTICES BY DISTINGUISHED

NON-PROFESSIONAL JOURNALS.

THE Physiological Articles in this work having attracted attention beyond the limits of the profession, the following extracts from Notices are selected from distinguished journals which are not medical, but in which the Notices were evidently written by those who had studied the work, and which, therefore, embody public opinion.

From the North American Review, April, 1863.

"This work covers the entire ground of physiology, pathology, and therapeutics, and, logical in arrangement, minute in subdivision, affluent in references to other books, and continually referring back and forward to its own pages, it constitutes an admirable system of medical science. This were ample praise. But in addition to this, the successive subjects are treated by Dr. Paine with great conciseness, indeed, but with great vigor and earnestness, with frequent originality,

and in a style which shows that, when his opinions coincide with those of others, they are yet his through the independent action of his own mind. Then, too, if he agrees with no one else, he is uniformly consistent with himself, his conclusions following legitimately from his premises, and his views on allied departments of science or art bearing tokens that they belong to the same system, and rest on parity of reason."

From the Methodist Quarterly Review, April, 1863.

"Of the two great schools, namely, the Chemical and the Vital, Dr. Paine is a leader if not the head of the latter." "From the high character of the chemical theorists, and the plausibility of their pretensions, they seemed, for a while, to carry with a rush every thing before them. Medical science was thus tending to a system of low

theoretic materialism. Against this torrent Professor Paine has stood firm as a column of adamant." "Whatever may be his peculiarities of belief, all parties must bear testi only to his learning, genius, individuality, and pure independence of mind."

From the American Quarterly Church Review, April, 1863.

"In the Appendix the Author attempts to demonstrate the substantive existence of the Soul and the Instinctive Principle upon physiological grounds. The demonstration is exceedingly able,

and refutes effectively, we think, the materialism of the day, by which infidels would rob the soul of its immortality."

From the Boston Review, March, 1863.

"Its strong points are a broad and thorough treatment of the whole science of physiology, pathology, and therapeuties; a sturdy conviction of the soundness of its positions; a clear understanding of the opposing theories; and a vigorous, classic, concise, and unflinching style of writing."

"In a labored supplementary dissertation he contends with great cogency for the distinct existence and immortality of the soul, against the materialists and all who, confounding reason with instinct, push us downward toward annihilation."

From the New York Evening Post, August 8, 1863.

From the New York Eve upon the New York Eve medical scholarship. The volume before us requires no praise. It is a most valuable magazine of therapentical sciences, containing, as it does, the results of thorough investigation which are here carefully digested and applied. The learned author discards utterly any dependence upon organic chemistry for the prosecution of physiological or pathological research, and proves his positions by quotations from Lehmann.

"The most curious chapter, for metaphysicians, will be found in the Appendix, where Dr. Paine has embodied an essay on the 'Soul and Instinct, physically distinguished from materialism."

"Many of the positions taken by Dr. Paine are original with him. He is a physician of extraordinary attainments; and his works have been liberally copied from at home and abroad."

From the New York Daily Times, February 7, 1863.

"Professor Paine's Institutes of Medicine are based on broad and prominent principles of Nature." "Solidism and vitalism,' the book opens, will form the basis of these Institutes;' and to the elucidation of these time-tried doctrines, and to their defense against Chemical Philosophy and kindred neologisms, he brings the results of long and severe investication and eminent knowledge. He does not scruple to enter the lists and try his lance against the glittering armor of Liebic and Humboldor, and it is apparent to every one that the blows are well aimed, and the weapon impelled by a stout arm, guided by a clear eye, with a vigcorous brain behind it." "We do not pretend to

commend the work to the Profession. It is already thoroughly appreciated there. But there are now such a large number of non-professional students and investigators in this field of research that we wish to call attention to this new edition of a standard professional book." "In a very entertaining chapter on the 'Rights of Authors' in which Professor Paine dissects the claims of those who pretend to have antedated him in the discovery of some valuable principles, and in the statement of some important theories, he clearly shows his priority in research, discovery, and promulgation of the doctrines in question."

From the Taunton (Mass.) Gazette, February, 1863.

range of its learning and the vigor of its logic. We feel, as we read, that Professor Paine is not only vast in his sweeps, but unerring in the return of his curves. As an inquiry into what is so far known of the treatment of diseases as to have been demonstrated by long and enlightened practice, this elaborate work is most thorough in its array of facts, and singularly vigorous in its reasoning. It is emphatically a student's book; and yet no one capable of drawing an inference from premises,

"This massive work is alike remarkable for the | and of understanding how premises should be established, can read these 'Institutes' without growing in wisdom on the subject, if he do not find cause to cast out some crude and perilous opinions which he had previously entertained. Certainly, so antagonistic are curative theories, that it behooves every man to inquire for himself; and nowhere can he look with more satisfaction for the legacies which all the ages have bequeathed to the healing art than in this volume."

From the Philadelphia Presbyterian Standard, February, 1863.

"Dr. Paine does not do himself justice, as this, instead of the seventh, is really the eighth edition

of his great work."

"After twenty years' acquaintance with the schools of Edinburgh, Dublin, London, and Philadelphia, we feel warranted in saying that we have seldom met with any single work that is better calculated to stimulate an active mind that is really and earnestly engaged in the pursuit of medical knowledge than in this work of Dr. Paine now before us. Dr. Paine grasps every subject with the

hand of a giant." "The student who masters this book, if he have a capacity to comprehend demonstration, will never confound our material organization with that which dwells within it."

"We commend this really learned, manly, and wonderously suggestive treatise to all our young medical friends; and in order that some hundreds of them may know our estimation of its value, we shall take care to have this, our judgment of its merits, made known to the medical schools of this city."

From the American Presbyterian, Philadelphia, 1863.

In a second notice of the seventh edition of the Institutes, the writer says that: "A careful examination of this work shows the author to have a fine mind, highly cultivated, and ardently devoted to the advancement of his profession. He seems to have read and carefully digested almost every thing of value written upon it. Truth is

ever the object before his mind, and while he states his own opinions strongly, we admire the fairness with which he presents the views of those opposed to him." "The principles of the work will be a safe guide to the active physician, and may be trusted in cases of doubt and danger."

From Zion's Herald and Wesleyan Journal, January, 1863.

"We commend the 'Institutes' to physicians and to scholars of all professions. It should be in

every public library."
"The arguments to show from physiology that

the mind is a spirit, and the revelation of its immortality is reasonable, are original and profound, and very strongly expressed."

From the New York Observer, January 7, 1863.

"The medical student makes the Institutes of Medicine his text-book, and every intelligent person who reads it with attention finds a field of knowledge opened up to his mind that constantly furnishes him most important and useful instruc-It is often said that when a man begins to

read medical books he imagines himself the victim of all the diseases he reads of. Such a philosophical work as this will not leave him liable to an evil like that, but he will learn those great principles on which health and life depend."

From the New York Sunday Times, January 11, 1863.

"Dr. Paine's discussion of the vital principle and its properties will deeply interest many a reador besides medical practitioners and students, and his whole treatment of the subject of organic phi-losophy will be found at once able, eloquent, eru-dite, and full of remarkable originality." "Physiology, pathology, and therapeutics, with all their

relative branches of study, are elaborately treated in these 'Institutes,' and an extraordinary amount of information is given on the subject of physio-logical and pathological chemistry, the production of animal sugar, the absorption and circulation of plants," &c.

From the New York Evening Express, January 10, 1863.

"A most valuable book the 'Institutes' must amusing and instructive one for the general readbe for the practical physician, as well as a most | er."

From the New York Christian Times, January 22, 1863.

**Criticism is not the thing required in respect to this learned and philosophical volume. It is sufficient that we call attention to this as the seviphysicians, and as a savan of whom the profession sufficient that we call attention to this as the serphysicians, and as a savan of whom the profession
enth edition of an opus magnum of the highest; is justly proud."

From the New York Commercial Advertiser, January 13, 1863.

"This seventh edition of the 'Institutes' is the brother physicians and their successors. Successful author's legacy, more valuable than rubies, to his will be be who studies and follows its teachings."

From the Congregationalist, Boston, January, 1863.

"The Institutes of Medicine is an invalidation repository of scientific information and a lasting monument of the author's industry, skill, learning, and genius. He enters on his work with the facility of an adept and the vigor of an athlete. Entertaining a lofty scorn of empiricism, he slowly gathers fact on fact, piling them up into a firm | suggestive and satisfactory."

"The Institutes of Medicine is an invaluable | foundation for the temple which he would rear, nouncation for the temperature which he would rear, whose solidity, proportions, and effect, we can not fail to admire." "To his opponents, as well as to his adherents, the book must be of an inestimable value. Symmetrical in plan, exhaustive in detail, clear in style, devoted in spirit, it is at once

From the Christian Intelligencer, New York, February, 1863.

"The 'Institutes' is a monument of learning; | promise of the wide and lasting influence it is yet and the reception it has already had is no empty to exert."

From the Chicago (Illinois) Journal, February, 1863.

Soul and Instinct, in which the substantive existence of the former and the principle of the latter are demonstrated, is one of abounding inter-

"To the unprofessional reader the essay on the oul and Instinct, in which the substantive extence of the former and the principle of the lat-

From the Maysville (Kentucky) Eagle, February, 1863.

"The 'Institutes' is a monument of his learning and industry. Although differing widely with the prominent modern pathologists in regard to many views of medicine, he does so with manliness and candor, and his own opinions are urged

with great learning, and with the utmost sincerity and fairness. It should be in the library of every reading physician, and especially prized in that, in addition to its being elaborate, vigorous, and learned, it is a home book,"

From the Presbyterian Witness, Cincinnati, Ohio, 1863.

""My aim, says Dr. Paine is truth." To what extent he has succeeded in his aim, there will, of course, be difference of opinion. In our judgment, however, he has succeeded in embodying in

his Institutes a vast amount of truth, sufficient to entitle the work to the confidence, and secure it the patronage, both of the Profession and of a generous and appreciating public."

From the Buffalo (N. Y.) Journal, 1863.

⁴⁴ Even to non-professional eyes a cursory glance over the pages of this great work reveals, to some extent, the herculean labor which its preparation must have involved. The work before us is not only a complete digest of all that is known of the limits of the digest of all that is known of the limits of the digest of all that is known of the limits of the digest of the state of the limits of the limit limitless subjects it discusses, but, venturing bold-ly beyond the sphere of previous explorations, Dr. Paine has brought in a harvest of discoveries, by

which science is enduringly enriched." "It is not necessary that we should say more in commendation of so noble a contribution to science. We make but few books like this in America, and such as are produced on this side the Atlantic, for the sake of our National fame, if for no higher reason, should be received with due pride and appreciation.

From the Worcester (Mass.) Palladium, February, 1863.

"The excellent portrait, prefixed to the 'Institutes, indicates the character of the man; one who is an acute observer, who takes no superficial view of subjects, but investigates deeply and wide-ly, finding the causes of phenomena, however profound may be the research required, and tracing those causes to all their consequences, however intimate or remote; with that moral courage, none too common among men, that reaches conclusions

emphatically its own, and has no hesitation in the arowal of convictions deliberately formed. From such intellectual power, cultivated mainly by its own effort, and acting upon the dictates of its own independent judgment, such a volume as this, where there is the requisite mental activity, comes as naturally as the ripe corn comes from the principle of life in the germinating seed."

COMMUNICATIONS TO THE AUTHOR.

As an example of letters which the author continues to receive, we submit the following extract of a letter from the eminent Von Dr. Professor N. Zdekauer, Physician to His Majesty the Emperor of Russia, dated St. Petersburg, April 19, 1867.

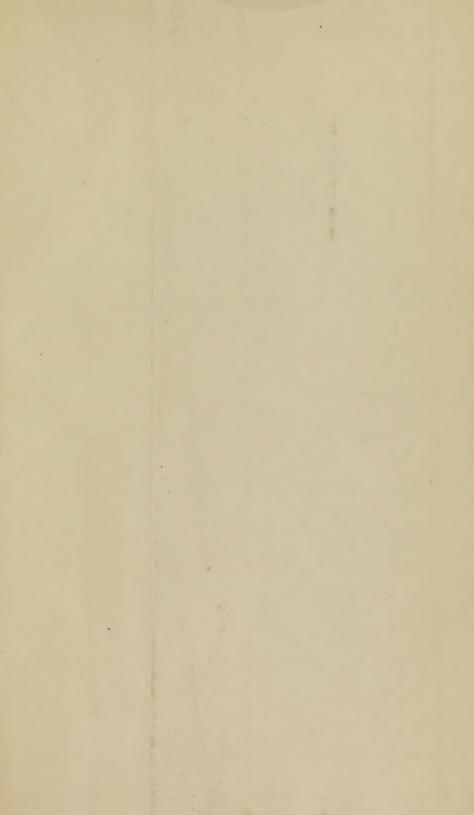

"Your valuable works are very often studied by me, and I look on them as on an Enchiridion of Medical Science and Philosophy. How wise and practical are your chapters on the Remedial Actions, on Sympathy, and all the chapters on Pathology! But your greatest merit is to have in a most rational manner treated about Vital Principles and Powers, contrary to the most material and dead-born tendencies of the newest authors."
